**SCOPE**

Iranian Journal of Veterinary Science and Technology (IJVST) is a peer-reviewed and multi-disciplinary journal that supports important research advances in veterinary medicine and subject areas relevant to veterinary medicine including anatomy, physiology, pharmacology, bacteriology, biochemistry, biotechnology, food hygiene, public health, immunology, molecular biology, parasitology, pathology, virology, etc. Contributions related to clinical sciences including large and small animal medicine, poultry disease, diseases of equine species and aquaculture are welcomed. Articles can comprise research in basic sciences, as well as applied veterinary findings and experimental studies and their impact on diagnosis, treatment and prevention of diseases.

ABSTRACT

The present study was conducted on 42 dogs with a histopathological diagnosis of skin neoplasia presented in the Shiraz University Veterinary Clinic from April 2012 to December 2017. All cases were reviewed, excluding the mammary gland neoplasms. The histopathological type, prevalence, sex, age, breed and site distribution of the neoplasms were described. In addition, previous studies on canine skin tumors from other geographic regions were evaluated and compared with the results of the present study. Fifteen different histopathological types of tumor were diagnosed. The prevalence of epithelial, mesenchymal, melanocytic and lymphohistiocytic tumors was 61.9%, 35.7%, 2.4% and 0 %, respectively. The three most common tumors were sebaceous gland adenoma (21.42%), squamous cell carcinoma (11.9%), and lipoma (11.9%). The incidences of these tumors were more than other researches. Although there is no obvious explanation for these geographical differences, the possible reasons may be the geographical locations, environmental influences, and the study population and breed. Terriers were the most common type of the dogs in this study (34.4%). The present findings about the dogs age and various skin tumors and the anatomical locations indicates that there is no significant variation in these important parameters among the Iranian dogs and dogs from other parts of the world.

UV: Ultraviolet
Introduction

Neoplastic conditions in dogs can involve the skin, which is the largest organ system of the body [1, 2]. Several studies have been published about the relative incidence, predilection sites, and the effects of age, sex and breed on different skin tumors of dogs from different geographic regions like Denmark [3], United Kingdom [4], USA [5], Greece [6], Grenada [7] and Zimbabwe [8]. It is important to demonstrate the regional variations in the occurrence and type of tumors that appear in dogs. For example, cutaneous histiocytoma has been the most frequently reported neoplasm in dogs in India and Zambia [9, 10]; lipoma was the most common skin tumor in dogs in Korea [11], and mast cell tumor ranked first in studies on dogs from Thailand, Denmark, Greece, Brazil, and Zimbabwe [1, 3, 6, 8, 12].

The exact reasons for these differences are not well understood. The reports show remarkable differences in various geographic regions that could be related mainly to climate, ultraviolet radiation (environmental carcinogenic exposure) and the breeds of dogs (differences in genetic susceptibility) as risk factors for some types of cutaneous tumors [13, 14].

According to our knowledge, there is no available and clear information on the canine cutaneous tumors in Iranian dogs. Thus, the aims of the present study were to identify the most common histologic types of canine cutaneous tumors, tumor frequency, age, sex and site distribution of a defined geographical area. These objectives can be used as a source of histologically confirmed cases for epidemiologic and laboratory studies. There are also comparisons between our findings with the results of surveys in other countries.

Results

Among the 42 neoplastic skin masses examined, fifteen different cutaneous neoplasms were recognized. Of these, 26 (61.9%) were of epithelial origin (8 types), 15 (35.7%) of mesenchymal origin (6 types), 1 (2.4%) of melanocytic origin (1 type) and no lymphohistiocytic origin were seen (Tables 1 and 2). Among the tumors, 8 (19.05%) were malignant whereas 34 (80.95%) were benign (Table 2).

The frequency, mean age in years, and male-to-female ratio of each neoplastic tumor type was shown (Table 1). The three most common tumors were sebaceous gland adenoma (9, 21.42%), squamous cell carcinoma (5, 11.9%), and lipoma (5, 11.9%). These three tumors comprising 45.22% of all cutaneous neoplasms diagnosed during the study (Table 1). The sebaceous gland adenoma was the most common tumor of all cutaneous neoplasms diagnosed during this period.

The mean age of affected dogs for all neoplasms except papilloma varied between 5.2 years (for hemangiopericytoma) and 11.5 years (for hepatoid gland adenoma and mast cell tumor) (Table 1). Tumors of epithelial and mesenchymal origin had a close mean age of occurrence (8.15 and 8.53 years, respectively).

Terriers were the most common type of dogs in this study (34.4%). Four of five cases of lipoma and half of the cases of sebaceous gland adenoma were observed in Terriers. Other breeds represented in this study in descending order of frequency were mixed breed dogs (sheep dogs) (9), German Shepherd Dog (7), Poodles (2), Pekingese (2), Labrador retriever (1), Great Dane (1), Maltese (1), Boxer (1), Shih Tzu (1), Miniature Pinscher (1) and Spaniel (1).

Skin tumors were most frequently located on the head and neck (16), followed in descending order by trunk (12), limbs (11), and multiple sites (3) (Table 3). Among the malignant tumors, 6 of 8 were found in the...

head and neck.

Indicative photomicrographs of some cutaneous tumors recorded in the present study are also presented (Figures 1-9).

Discussion

The results of this survey in Shiraz are compared with those from Zimbabwe, Greece, Denmark, Korea, Thailand and the USA (Table 4). In the present study, the most common tumors were sebaceous gland adenoma, squamous cell carcinoma, and lipoma. These three tumors comprised near half of all diagnosed cutaneous neoplasms. The incidences of these tumors were far more than the other researches [1, 4-6, 8, 11, 12]. There is no obvious explanation for these geographical differences. The squamous cell carcinoma prevalence (11.9%) was close to a survey in Zimbabwe (15.4%) [8]. Squamous cell carcinoma was the second most common tumor in both studies. A possible explanation may be in the environmental influences. Zimbabwe and Shiraz lie in the subtropics and most dogs are kept outdoors and therefore have greater exposure to sunlight. Other tumors, such as haemangiosarcomas and hemangiomia, that have been associated with increased exposure to UV light in humans and domestic animals [6] were also seen in both studies. However, a study in tropical Queensland found no increase in UV light-associated tumors number compared with other regions [15]. The discrepancies between these data and the results obtained from previous studies in relative incidence of these diagnosed tumors may be related mainly to differences in the classification system, the diagnostic criteria, the geographical locations and environmental influences, and the breed and study population.

The majority of the diagnosed tumors in the current study were benign (80.95%) in nature, and this finding was in accordance with earlier reports [16, 17]. The percent of malignant tumors (19.05%) was less than the percent detected in Zimbabwe (37%) and Denmark (42.48) [3, 8].

Among skin tumors, 61.9% and 35.7% were of epithelial origin and mesenchymal origin respectively. Prevalence of skin epithelial versus non-epithelial tumors in the dog varied in different studies. In many studies [8, 18], the most common tumors (around 45-50%) were mesenchymal origin following by epithelial origin (near 40%) and melanocytic origin (5-9%). In comparison to these researches, epithelial tumors were higher in the present study. In Greece, epithelial tumors were the most common (like our finding), and constituted 48% of all skin tumors and mesenchymal tumors constituted 40% [6]. The observed differences in different countries may be a reflection of canine breed population and environmental influences.

For all skin neoplasms, except papilloma that occurs in young dogs [18], the mean age of affected dogs (Table 1) falls within the common range for the occurrence of most neoplasms in dogs, that is, 6 to 14 years [19]. According to our data, the mean age of dogs affected by skin tumors is 8.22 years. It is close to the results of similar researches in Zimbabwe [8], Korea [11], and Germany [20].

Head and neck were the most frequent location for skin tumors, followed in descending order by trunk, limbs, and multiple sites (Table 4). In many researches, trunk detected as the most common site of skin tumors; or greater prevalence of skin tumors found in female dogs. These kinds of data were determined by including mammary tumors and the high prevalence of mammary neoplasms in bitches and also different classifications used by researchers [19]. In the present study, the mammary gland neoplasms were excluded. Due to a limited number of cases for each tumor, drawing valid conclusions on the sex, age, breed and anatomical locations predilection for the most frequently diagnosed tumors were not possible in our overall population. However, the present finding about the dogs age and various cutaneous tumors and anatomical locations shows that there is no significant difference in these important parameters among the Iranian dogs and dogs from other parts of the world.

Twelve breeds, including mixed breed dogs, were represented in this study. Terriers were the most common type of dogs who presented with skin tumors, followed by mixed breed dogs and German Shepherds. Terriers are the common and popular breed in Iran. The differences on the incidence of skin tumors might have appeared due to different popularity of certain breeds in certain geographical regions. Since canine population figures for Iran are not available, relative prevalence among different breeds could not be determined; while there may be a predisposition for cutaneous tumors among some breeds.
RESEARCH ARTICLE

It is necessary to document the prevalence of different tumors in various geographic areas so that more definitive information may be gathered for future use. Documented knowledge on the incidence and type of tumors helps veterinary practitioners to identify an appropriate therapy and anticipate an appropriate prognosis. After an accurate clinical examination, consideration of documented information on sex, age, breed and the histopathological report, tumors can be diagnosed in a reasonable amount of time and clinicians will be able to determine and decide on a proper treatment, and anticipate an appropriate prognosis for many patients.

This study was entirely based on clinical cases submitted from the Veterinary Medical Teaching Hospital of Shiraz University. Therefore, it is anticipated that the results of this study will reflect the prevalence and distribution of various skin tumors in the Iranian dog population. Furthermore, this result would serve as an important reference in future researches. To our knowledge, this kind of information has not been published previously for the Iranian dog population.

Based on the present finding, most of the cutaneous neoplasms in dogs from Shiraz (Iran) were epithelial-origin and the most common tumors were sebaceous gland adenoma, squamous cell carcinoma, and lipoma. Although there is no obvious explanation for differences between these results and similar research findings in other countries, the possible reasons may be the geographical locations, environmental influences, and the study population and breed. The present finding about the dogs ages and various cutaneous neoplasms and anatomical locations reveals that no significant variation is in these parameters among Iranian dogs and dogs from other parts of the world.

Material and methods

The present study was conducted on 42 dogs of different breeds, sex and age group with skin tumors presented to the Shiraz University Veterinary Clinic from April 2012 to December 2017. Only dogs living in the Shiraz region at the time of collection of the specimens were included in the survey. All cases with a histopathological diagnosis of skin neoplasia were reviewed, excluding the mammary gland neoplasms.

Biopsies have been taken from suspected sites under general anesthesia. Specimens were fixed in 10% neutral buffered formalin, embedded in paraffin and sections stained with haematoxylin and eosin. Tumors were diagnosed and classified according to the current World Health Organization (WHO) classification of animal tumors [21, 22]. History relating to sex, breed, age, and site of the tumor were obtained. Initially, the histopathological type, prevalence, sex, age and site distribution of the neoplasms were described. The neoplasms were grouped into 4 broad classes, namely epithelial, mesenchymal, melanocytic and lymphohistiocytic. Location of the tumor on the body was categorized into 4 groups: head and neck, trunk, limbs, and multiple sites.

In addition, published studies on skin tumors of dogs from other geographic regions were evaluated and compared with the results of the present study.

Experimental infection of pheasants with a velogenic chicken isolate of Newcastle disease virus

Ramezan Ali Jafari, Anahita Rezaie, Zahra Boroomand, Mansoor Mayahi, Reza Zare

ABSTRACT

Newcastle disease (ND) is a highly contagious infection of many avian species, causing enormous losses in poultry production worldwide. The objective of this study was to reveal the clinical feature, virus shedding, and immune response following infection with a velogenic chicken isolate of Newcastle disease virus (NDV) in susceptible and vaccinated pheasants. Eighty-day-old pheasant chicks were allotted to four groups. At 30 days of age, the birds in groups 1 and 3 were vaccinated with B1 strain via eye drop. Two weeks later, each bird in groups 1 and 2 was inoculated with 100 μL (50 μL/eye) of NDV-infected allantoic fluid containing 10⁵ EID₅₀ of viral inoculum. All groups were inspected daily for three weeks. Swab samples were taken at different time points, and verified for NDV infection by using reverse-transcription polymerase chain reaction (RT-PCR). Serological examination was also made by haemagglutination-inhibition assay. Clinically, watery mucoid feces was observed only in one case among the vaccinated challenged birds, whereas the unvaccinated challenged birds showed anorexia, mild depression and head deviation. Out of 20 birds in group 2, one case (5%) died. Based on RT-PCR, virus shedding was only observed among the unvaccinated birds from 5 to 14 days after challenge. The NDV was detected more in tracheal swabs (40%) than in cloacal swabs (30%). The infected birds showed a high seroconversion. In conclusion, the velogenic NDV circulating in Iranian chicken flocks has a low pathogenicity for pheasants, and ocular vaccination with B1 strain could provide a good protection.

Newcastle disease (ND) is a highly contagious and fatal disease affecting at least 241 species of domestic and wild birds of both sexes and all age groups [1]. The causative agent is a virulent virus of the avian paramyxovirus serotype I of the genus belonging to the family Paramyxoviridae [2]. Velogenic Newcastle disease virus (NDV) is endemic in many countries of the Middle East, Africa and Asia [3]. The inclusion of ND in the list of notifiable diseases by World Organization for Animal Health (2008) is indicative of its paramount economic impact on the worldwide poultry industry [2]. Among poultry, chickens are the most susceptible, showing the most clinical signs, and ducks are the least susceptible, showing the least clinical signs. Nonvaccinated pheasants are highly susceptible with clinical signs similar to those observed in chickens [3].

The first outbreaks of ND were observed in chickens in 1926 in Java, Indonesia, and Newcastle-upon-Tyne, England [3]. Then, NDV was spread throughout the world, and affected other avian species such as turkeys and quails [4,5]. Several outbreaks of NDV have been also reported in pheasants in East Anglia [6], Iraq [7], Great Britain [8], Denmark [9], and South East England [10]. In Iran, NDV is endemic in different parts of the country, causing enormous losses due to high mortality, sub-optimal production, slaughterhouse condemnation of carcasses, and high prevention and treatment expenses. In recent years, outbreaks of ND have been occasionally observed in different avian species in Iran, including Japanese quail [11], ostrich [12], exotic caged birds [13], and broiler chickens [14]. During 2012-2013, some outbreaks with heavy losses occurred among commercial broiler chicken flocks located in southwest Iran. The isolated viruses were classified as genotype VII, and subsequently to subgenotype VIIId [15].

Today, pheasant is extensively reared in several countries of the world as a game bird or for the purpose of human consumption. In recent years, commercial production of pheasant has increased in some regions of Iran, and a part of protein demands of Iranian people is provided with the meat of this bird. The NDV may be easily transmitted from one avian species to another, and some outbreaks in pheasants were epidemiologically related to the spread of the virus from chickens [6] and feral migratory birds [9]. Considering that viruses emerging from field strains may possess relatively new features, this study was conducted to investigate the clinical manifestations, virus shedding and serological responses following infection with a velogenic chicken isolate of NDV in susceptible and vaccinated pheasants.

Results

Clinical signs

No morbidity or mortality was observed in unchallenged pheasants. The vaccinated challenged birds exhibited watery mucoid feces only in one case, whereas the unvaccinated challenged birds showed anorexia, mild depression and head deviation (Figures 1 and 2). Almost one-fourth of these birds became morbid, but 1 (5%) out of 20 pheasants died at 10 days postinoculation. Clinical symptoms appeared 7 days postinoculation and continued by 12 days after challenge.

Virus shedding

An attempt to detect the virus was made for a period of three weeks, and the results of the PCR are presented in Figure 3. Out of 10 birds in group 2 which were sampled after challenge, 6 cases (60%) shed the NDV through respiratory and/or intestinal tracts from 5 to 14 days postinoculation. The NDV was detected more in tracheal swabs (40%) than in cloacal swabs (30%). The tracheal swabs were virus-positive at 5 and 10 days post-challenge, but the cloacal swabs were virus-positive at 10 and 14 days. The NDV was not detected in samples obtained from the other groups (Table 1).

Serological examination

The antibody response of pheasants to vaccination and or challenge with velogenic NDV is summarized in Table 2. The HI titers of the serum samples of all groups were negative (i.e., < Log23) before vaccination. This status continued in the birds of group 4 by the end of the experiment, whereas a significant seroconversion occurred after vaccination or challenge in the other groups (p < 0.05). In group 3, the HI titer increased significantly after vaccination (p < 0.05), but its change was not significant from 14 to 28 days post-vaccination (p > 0.05). After challenge, the HI titers increased in groups 1 and 2; although its elevation was only significant (p > 0.05) in group 2.

Discussion

The NDV continues to be a major threat to the poultry industry. After infection with velogenic NDV, the nonvaccinated birds may die suddenly with no clinical signs and with a death rate of 100% [3], although the severity of the disease observed with any given virus greatly varies depending on host parameters, including species, breed, age and immune status,

1. At 30 days of age, pheasants in vaccinated groups received B1 strain vaccine via eye-drop. Two weeks later, each bird in challenged groups was inoculated through ocular route with $10^6$ EID$_{50}$ of viral inoculum.

2. At each time point, two birds per group were sampled and examined for NDV infection by RT-PCR.
cointfection with other organisms, environmental and nutritional conditions, and route of exposure [1,16]. The virus used in this study was isolated from an outbreak of ND in a vaccinated chicken flock with a high mortality, and was characterized as a velogenic strain based on the sequencing of the F protein cleavage site. However, in this experiment, only one of 20 birds in group 2 died and the other morbids recovered rapidly. To our knowledge, there is no information regarding the experimental pathogenicity of NDV for pheasants to be compared with our results. But, the lower severity of the disease observed in pheasants can be associated with their less susceptibility, as well as route of infection (i.e. experimental vs natural) [2,10]. In a similar study performed by Wakamatsu et al. (2006), chickens challenged with velogenic NDV exhibited clinical signs at 2 days after inoculation and experienced a mortality rate of 100%, whereas commercial turkeys developed the clinical disease later exhibiting a mortality rate of 100%, whereas commercial turkeys developed the clinical disease later and was characterized as being nonspecific [2]. On the other hand, a sudden seroconversion was observed in the other groups, implying the induction of active immunity by vaccinal or challenging virus. In group 3, mean HI titers of 4.5-4.8 (Log2) were resulted from vaccination, but did not change significantly during 14 to 28 days postvaccination. In a similar study performed by Schmidt et al. (2008), ocular vaccination of 10-day-old pheasants with B1, Ulster 2C, or LaSota strains [18]. The general clinical signs, including anorexia, lethargy, and head deviation observed in the unvaccinated challenged birds are the typical of the disease. They were all reported previously in natural infections of pheasants with NDV [6,7,17,19].

RT-PCR is one of the reliable laboratory techniques facilitating a rapid diagnosis by detecting NDV virus in clinical specimens [2]. In the current study, NDV was first detected in tracheal swabs obtained from nonvaccinated challenged pheasants at 5 days postinoculation before the appearance of the clinical signs (i.e., 7 days after inoculation). In our previous work, the Wishard bronze poults experimentally infected with highly virulent NDV of chicken isolate shed the virus 2 days earlier than the exhibition of clinical signs [20]. Wakamatsu et al. (2006) isolated NDV from swab samples of infected turkeys at 2 days postinoculation, whereas the onset of the disease was at 6 days postinoculation [16]. Moreover, in the present study, the tracheal swabs had a higher virus detection rate (4/10), compared to the cloacal swabs (3/10). This is somewhat consistent with the results reported by the previous studies, in which NDV was more frequently isolated from oral swabs than from cloacal swabs [16,21]. The detection or isolation rate of NDV may be influenced by the tropism of the virus. In an experimental study performed by Perozo et al. (2008), VG/GA strain of NDV was detected more in samples obtained from the intestinal tract of broiler chicks, whereas LaSota strain was detected more in samples taken from respiratory tracts [22]. Nevertheless, some studies have demonstrated the lack of sensitivity in detecting the virus in fecal samples, because they contain more extraneous organic material that can interfere with RNA recovery and amplification by PCR, suggesting that tracheal or oropharyngeal swabs are often the specimens of choice [2]. In the present study, virus shedding was not observed in vaccinated challenged pheasants. This is likely to be associated with less sensitivity of virus detection than isolation method, the small number of birds sampled at any time point after challenge, and or less susceptibility of pheasants to NDV in comparison with chickens, however additional studies are needed to clearly explain this finding.

As shown in Table 2, the HI titer in group 4 was lower than log3 before vaccination, and remained constant during the experiment, which can be regarded as being nonspecific [2]. On the other hand, a sudden seroconversion was observed in the other groups, implying the induction of active immunity by vaccinal or challenging virus. In group 3, mean HI titers of 4.5-4.8 (Log2) were resulted from vaccination, but did not change significantly during 14 to 28 days postvaccination. In a similar study performed by Schmidt et al. (2008), ocular vaccination of 10-day-old pheasants with B1, Ulster 2C, or LaSota produced mean HI titers of 4.2-5.0 (Log2) at 24 days of age [18]. In group 2, a higher HI titer (7.1) was found after challenge by velogenic NDV. Aldous et al. (2007) reported HI titers of 2-2.5a (tested with 8 HAU of antigen) in pheasants suffering from an outbreak of ND [10]. Piacenti et al.

* Thirty days of age. Before challenge. Two weeks after challenge.
genic NDV circulating in Iranian chicken flocks has a contamination with B1 strain along with biosecurity could low pathogenicity for pheasants, and that ocular vaccination with Hitchner B1 will result in production of lachrymal IgM, IgG, and IgA due to the replication of virus in the Harderian gland, which could be prevented by the presence of maternal IgG in lachrymal fluid [24].

These findings indicate that serum antibody alteration in pheasants following exposure to NDV is rapid and very similar to that in chickens and turkeys. In infection of chickens with NDV, antibodies usually are detectable in the serum within 6-10 days and reach the peak after 2-4 weeks [22,24].

In conclusion, the results indicated that the velogenic NDV circulating in Iranian chicken flocks has a low pathogenicity for pheasants, and that ocular vaccination with B1 strain along with biosecurity could provide a good protection.

Material and methods

The velogenic NDV used in this experiment was isolated from a broiler chicken flock in southwest Iran during an outbreak in 2013. Based on nucleotide sequence, the virus was previously characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15]. Initially, the virus was propagated twice in 9-day-old embryonated chicken eggs and characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15]. Initially, the virus was propagated twice in 9-day-old embryonated chicken eggs and characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15]. Initially, the virus was propagated twice in 9-day-old embryonated chicken eggs and characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15]. Initially, the virus was propagated twice in 9-day-old embryonated chicken eggs and characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15]. Initially, the virus was propagated twice in 9-day-old embryonated chicken eggs and characterized as genotype VII (subgenotype VIIId), and assigned an accession number of NDa:KP347437 [15].

Inoculation of birds from each group before inoculation and at 2, 5, 10, 14, and 21 days postinoculation. The blood samples were left to coagulate at room temperature for 8 h, and then centrifuged at 2000 rpm for 5 min. The collected sera were stored at -20°C until examined by HI test.

Reverse-transcription polymerase chain reaction

The swab samples were individually placed in microtubes containing 250 μl phosphate-buffered saline (PBS). After removing them from the microtubes, the RNA extraction was performed using the RNX™-Plus Kit (CinaGen, Tehran, Iran) according to the manufacturer’s protocol. The isolated RNAs were directly used for the RT-PCR or stored at -70 °C. The partial F gene, including the cleavage site sequence, was amplified using a pair of specific primers. The primer sequences were TT GAT GGC AGG CCT CTT GC and GG AGG ATG TTG GCA GCA TT [14]. The complementary DNA (cDNA) was synthesized using BioNeer RT PreMix kit (BioNeer Corporation, South Korea) according to the manufacturer’s instruction. The RT-PCR assay was carried out in a 20 μl reaction volume consisting of 2 μl of 10x PCR buffer, 0.2 μl of 10 mM dNTPs, 1 μl of each primer (20 pmol/ml), 0.2 μl Taq DNA polymerase (5U/ml), 0.6 μl of 50 mM magnesium chloride, 10 μl distilled water, and 5 μl cDNA dilution. The RT-PCR conditions included initial denaturation at 95°C for 3 min, followed by 40 cycles of 95°C for 30 sec, 55°C for 60 sec, 72°C for 60 sec, and a final extension at 72°C for 10 min. The RT-PCR products with 330 base pairs (bp) were subjected to electrophoresis using 1.5% agarose gel. The NDV-infected allantoic fluid from our previous work was used as positive control, and distilled water was employed as negative control. In addition, a 100-bp DNA marker was used in electrophoresis for determining the RT-PCR product size.

Haemagglutination-inhibition test

The sera obtained by centrifugation of the samples were left in a water bath at 56°C for 30 min. Then, they were assessed for haemagglutination-inhibiting antibodies using 4 HA units of NDV antigen and two-fold serum dilutions as recommended by Thayer and Beard (2008) [26]. The results were expressed as Log2.

Statistical analysis

All data were analyzed in SPSS software (Version 24.0., Armonk, NY: IBM Corp.) using one-way analysis of variance. Differences showing p<0.05 were considered statistically significant [27].

ABSTRACT

Growth hormone has mitotic and anti-apoptotic effects which may increase proliferation and transformation of cells when it is expressed aberrantly. This study investigated the effects of resistance training and growth hormone injection on circulating IGF-1, IGFBP-3 levels and IGF-1/IGFBP-3 ratio in male Wistar rats. Thirty-two male Wistar rats were randomly assigned to a control group (C, n = 8), a resistance training group (RT, n = 8), a growth hormone injection group (GI, n = 8) and a resistance training + growth hormone injection group (RG, n = 8). The resistance training protocol comprised of climbing a ladder (5 days/week, 3 sets/5 reps) while carrying a weight suspended from the tail. The growth hormone (2 mg/kg/day, 5 days/week) was injected before an exercise session. Serum IGF-1, IGFBP-3 levels, and IGF-1/IGFBP-3 ratio were measured after 8 weeks. One-way ANOVA analysis was used for comparison of serum IGF-1 and IGFBP-3 levels between groups. Serum IGF-1 levels and IGF-1/IGFBP-3 ratio significantly decreased, but serum IGFBP-3 levels showed no significant change in the RT group compared to the C group. Also, both serum IGF-1 and IGFBP-3 levels and IGF-1/IGFBP-3 ratio in GI and RG groups significantly increased compared to the other groups. In conclusion, resistance training decreases serum IGF-1 levels and/or IGF-1/IGFBP-3 ratio in normal condition. On the other hand, the growth hormone injection with and without the resistance training increases serum IGF-1 levels and IGF-1/IGFBP-3 ratio which could be noted as a condition with a higher risk of neoplasm.

Resistance training; Growth hormone injection, IGF-1, IGFBP-3, Cancer
Introduction

Doping is a common phenomenon in the sports which has become more popular among different groups of people from adolescent and youth to non-elite and elite athletes, as well as non-sporting contexts by individuals who try to improve their appearance (1). Growth hormone (GH) is one of the doping agents that is used considerably for its anabolic and lipolytic properties (1, 2). GH stimulates the liver to produce insulin-like growth factors (IGFs), six common IGF binding proteins (IGFBP1-6) as well as other binding proteins (IGFBP7-10) which are discovered more recently (3). One of the main growth factors is IGF-1, which is an endocrine and auto/paracrine peptide expressed in the majority of cell types (4). GH affects the tissues by IGF-1 which stimulates mitosis and inhibits apoptosis. IGF-1 binds to its tyrosine kinase cell-surface receptor (IGF-1R) and activates [at least] two main signal-transduction pathways: 1) GTPase Ras-Raf-ERK/MAPK pathway and 2) PI3K/AKT pathway. Activation of these pathways stimulates proliferation and inhibits apoptosis which may lead in some conditions to malignant neoplasms (5).

Six types of IGFBPs have been known. IGFBPs act as important agents by attaching to IGFs and protect tissues from their undesirable effects. IGFBP-3 is the most abundant (more than 90%) IGF binding protein in circulation that modulates IGF-1 actions by enhancing and inhibiting IGF-1 bioavailability (6). Also, IGF-1 has an important role in the transformation and proliferation of cancer cells (7-10). In most cases, the elevated IGF-I concentrations are considered beneficial; however, cancer remains a significant exception. Some studies have shown that the increment of circulating IGF-1 levels or IGF-1/IGFBP-3 ratio and decrement of circulating IGFBP-3 levels are associated with higher risks of cancer. High levels of IGF-1 significantly increase the risks of colorectal (11), breast (9), and prostate cancers (7, 8). At the same time, researchers determined that IGFBP-3 which binds to IGF-1 seems to neutralize it and reduce the risk of these malignancies (11). Circulating IGF-1 is positively associated with breast cancer risk and this association is not substantially modified by IGFBP-3 (9). In recent studies, high and normal plasma of IGF-1 and low levels of IGFBP-3 were independently associated with a greater risks of prostate cancer (7, 8, 12), premenopausal breast cancer (10, 13), lung cancer (14), bladder cancer (15) and colorectal cancer (16, 17). Therefore, optimizing the levels of IGF-1 and IGFBP-3 might decrease the risk of several cancers.

Physical activity is another potential mediator which influences the GH-IGF-1 axis. The increases, decreases, and no changes in circulating IGF-I and IGFBP-3 levels after both acute and chronic exercises have been reported (18-24), and such equivocal findings prevent definitive conclusions. Moreover, the effects of GH injection with resistance training on circulating IGF-1 and IGFBP-3 levels have not been studied.

Thus, the aim of this study was to examine the effects of 8-week GH administration with and without resistance training on circulating IGF-1 and IGFBP-3 levels in Wistar male rats.

Results

Compared to the control group, serum IGF-1 concentration significantly decreased in RT group (p = 0.048), while it significantly increased in GI (p = 0.001) and RG (p = 0.001) groups (Figure 1). Furthermore, serum IGFBP-3 concentration did not show any...
significant changes in RT group (p = 0.93). In contrast, serum IGFBP-3 concentration significantly increased in GI (p = 0.003) and RG (p = 0.011) groups, compared to the control group (Figure 2). In addition, the IGF-1/IGFBP-3 ratio was significantly lower in the RT group (p = 0.001). On the contrary, the ratio of IGF-1/IGFBP-3 was higher in both GI (p = 0.001) and RG (p = 0.001) groups compared to other groups (Figure 3).

**Discussion**

We have examined the response of circulating IGF-1 and IGFBP-3 levels to GH injection with resistance training. The results of our study showed that resistance training reduced serum IGF-1 concentration. Some studies have already reported that acute resistance and endurance exercise increase serum IGF-1 concentration temporarily, which typically returns to baseline after 10 to 15 minutes (20, 23, 25, 26). However, other studies have demonstrated that chronic exercise training causes an increase (18, 21, 27), no change (28, 29), or a decrease (24, 30, 31) in circulating level.
of IGF-1, which is equivocal. Nindl et al. stated that although local IGF-1 is up-regulated with both acute and chronic exercises, circulating IGF-1 may actually decrease (32). The decrement of circulating IGF-1 in this study might be due to the anabolic role of IGF-1. Decreased circulating levels of IGF-1 in response to short-term chronic training (>12 wk), might be related to neuromuscular anabolic adaptations (32). It has been suggested that physical activity might increase the uptake of IGF-1 into peripheral tissues (33) and central nervous system (34). On the other hand, GH injection caused an increment in IGF-1 with and without resistant training. Recently, a positive correlation between the level of IGF-1 and the risks of several cancers such as colorectal, breast, prostate, lung cancer was found (35). According to cell proliferation and apoptosis inhibitor roles of IGF-1, previous studies have indicated that increased circulating IGF-1 level, decreased circulating IGFBP-3 and/or increased IGF-1/IGFBP-3 ratio might be involved in the commencement of these cancers (5). The consequence of binding IGF-1 to its receptor (IGF-1R) is the phosphorylation of insulin receptor substrate -1 (IRS-1). Subsequently, phosphoinositide 3-kinase (PI3K) is activated and increases phosphatidylinositol 3,4,5-tri-phosphate (PIP3), which activates the critical protein AKT/PKB through phosphorylation. As a result, the AKT protein stimulates the release of anti-apoptotic protein Bcl-2 from bad and activates protein synthesis through mTOR. All these actions are related to PI3K/AKT pathway of IGF-1 signaling which is ultimately responsible for cell death prevention (5).

Simultaneously, IGF-1 signaling increases cell proliferation through the Ras/MAPK pathway. After IGF-1 binding to IGF-1R and activating IRS protein SHC, GTPase Ras can stimulate Raf. Raf activates a kinase cascade which leads to the activation of mitogen-activated protein kinases (MAPKs), ERK1 and ERK2. Afterward, these MAPKs phosphorylate and activate multiple targets, in particular, the transcription factor ELK1 which increases gene expression and leads to cell growth (5). The imbalance between these pathways may result in the creation of neoplasm.

Secondly, we have found that circulating IGFBP-3 did not show any significant changes after resistance training. In spite of this, GH injection increased circulating IGFBP-3 levels with and without resistance training. IGFBPs are crucial regulators of IGF-1 actions and alter plasma levels of free IGF-1 without affecting total IGF-1 (4). It has been shown that resistance exercise changes the concentrations of IGFBPs which affects the biological activity of IGF-1 (21). IGFBP-3 is the most abundant protein that carries IGF-1, and lowers the free concentration of IGF-1 and protects IGF-I from degradation (36). The results of previous studies are also inconsistent with the effects of exercise training on circulating IGFBP-3 levels (23, 26, 27, 37). Nishida et al. showed that after 6 weeks of aerobic training, circulating IGF-1 levels decreased by 9% and IGFBP-3 did not change significantly (30). Nindl et al. observed a significant increase of IGFBP-3 after resistance exercise and a decrease to the baseline during the next 13 hours (38). Chicharro et al. discussed that 3 weeks of endurance competition did not change circulating IGFBP-3 levels, but it decreased IGF-1 levels (31). These glaring inconsistencies between studies might be due to the type of exercise, training volume, duration of the intervention and age, training background and nutritional status of participants (29, 32).

Finally, in the present study, resistance training decreased IGF-1/IGFBP-3 ratio, whereas GH injection with and without resistance training increased IGF-1/IGFBP-3 ratio. It has been stated that the IGF-1/IGFBP-3 ratio is a biomarker for bioavailability of circulating IGF-1 levels (39). Thus, decreased or increased IGF-1/IGFBP-3 ratio might be related to a lower and higher risk of cancer, respectively.

The results of the present study led us to conclude that resistance training decreases circulating IGF-1 levels and/or IGF-1/IGFBP-3 ratio in normal condition. On the contrary, GH injection with and without resistance training increases circulating IGF-1 levels and/or IGF-1/IGFBP-3 ratio which could be considered as a condition with a higher risk of neoplasm. Further studies are required to extend these results in order to discover the exact resistance training effects on IGF-1 and IGFBP-3 concentration, and to examine the risk of cancer types after GH injection which increases the circulating IGF-1 levels and/or IGF-1/IGFBP-3 ratio.

Material and methods

Animals

Thirty-two Wistar male rats, 12 weeks of age, were purchased from Razi Vaccine and Serum Research Institute of Mashhad. All rats were randomly divided into four groups. Each day, all the animals were injected subcutaneously with either GH or saline (5 times per week for 8 weeks). GH was injected 1 h prior to the exercise. Group C was injected with saline using the same method used for the GH injection groups. Group RT was injected with saline and subjected to resistance training. Group GI was injected with human recombinant growth hormone (Genotropin, Germany) with a dose of 2 mg/kg (BW) 5 days per week. Group RG was injected with human recombinant growth hormone and also subjected to resistance training. All rats were weighed weekly, and the hormone dose was adjusted according to body weight. All rats were housed under controlled conditions and had unlimited access to water and food pellets. The animals’ room temperature was maintained at 22 ± 1°C with a 12 h light/dark cycle. Experimental protocols were approved by the Institutional Animal Ethics Committee of Ferdowsi University of Mashhad (Ethic code: IR.MUM.IJVST 2019-1 (20) DOI:10.22067/veterinary.v111i1.78504
Resistance training

After the first week of adaptation, training protocol started, rats were trained 5 days a week for the next 8 weeks. Resistance training was accomplished by using a 1 m high ladder with 2 cm grid steps and an 85° grade. In their first week, rats were familiarized with climbing up to the top cage with and without weight on their tails. The weight, in an acryl tube, was attached to the tail with a plastic belt and tapes. Rats started their climbing from the bottom of the ladder and they were forced to climb up to the top by touching and shouting. Training sessions were started with the intensity at 50% of each rat’s bodyweight and increased (10% per week) gradually throughout the eight weeks of the training period. The resistance training consisted of three sets of five repetitions with a one-minute rest interval between the repeats and two minutes between the sets. This procedure was repeated until either the rat finished all three sets of training or failed to climb the entire length of the ladder (40).

Measurement of IGF-1 and IGFBP-3

Food was withheld for 12 h, and GH or exercise was withdrawn 72 h before the rats were anesthetized with 75 mg/Kg ketamine and 25 mg/Kg xylazine and killed. The serum was collected by centrifugation at 3000 RPM for 15 min at 4 °C and then stored at −20 °C until the analysis commenced. Serum IGF-1 and IGFBP-3 levels were measured by ELISA kits (Hangzhou East biopharma, Elisa Kits, CAT.NO: CK-E30653- E91558) according to the manufacturer’s protocol with a lower limit of detection of 1.55 ng/ml and 0.93 ng/ml, respectively.

Statistical analysis

The Shapiro-Wilk test was applied to display the normality of data distribution. The mean of circulating IGF-1 and IGFBP-3 levels and IGF-1/IGFBP-3 ratio were compared by One-way ANOVA analysis. The Tukey’s test was used post hoc to identify significant differences between groups. p < 0.05 was taken to denote statistical significance. Data were analyzed using SPSS software (version 20, SPSS Inc). All data are reported as mean (± SD). Significant differences between groups are shown as p < 0.05.

ABSTRACT

Anorexia is a part of the acute phase response (APR). Lipopolysaccharide (LPS) is frequently used to mimic APR and induces anorexia. The mechanism underlying anorexia associated with APR in chicks is not well understood. In the present study, the possible involvement of corticotrophin-releasing factor (CRF) on anorexic effects of LPS in neonatal chicks was investigated. For this aim, different doses of LPS were administrated via both intracerebroventricular (ICV) and intraperitoneal (IP) routes in order to assess its effects on chick’s food intake. Subsequently, the effect of ICV injection of astressin, a CRF receptor antagonist, on anorexia induced by ICV and IP administration of LPS was investigated. Food intake was significantly decreased following either central or systemic administration of LPS. ICV co-injection of astressin and LPS significantly diminished anorexic effects of central LPS. However, anorexia induced by peripheral LPS was not attenuated by central injection of astressin. These data indicated that the brain CRF receptors are involved in central LPS-induced anorexia in chicks.

IP: Intraperitoneal
Introduction

Energy homeostasis mechanisms are complicated and also in part different in animal species, including birds (1, 2). Similar to mammals, under physiological conditions hypothalamic nuclei play a crucial role in chick energy homeostasis (3). Hypothalamic homeostatic functions including appetitive and feeding behavior are extensively affected by immune agents (4, 5). Indeed, infectious challenges initiate acute-phase response (APR), a systemic defense mechanism, which is commonly reflected by immunological, physiological, and behavioral disturbances (6, 7). The behavioral changes are known as “sickness behavior,” and are represented by depression, changes in motivational state, fever and the decrease in food intake namely illness anorexia (8). Lipopolysaccharide (LPS), an endotoxin matter of cell surface of gram-negative bacteria, has been widely used as an experimental inflammatory model for evaluation of possible underlying mechanism(s) of anorexia in different species (9). LPS motivate expression of pro-inflammatory cytokines and anorexia-related agents, including corticotrophin-releasing factor (CRF) (10, 11). CRF plays an important role in stress responses such as changes in the hypothalamic-pituitary-adrenal axis, autonomic nervous system, immune system, and behavior (12, 13). These actions of CRF are mediated through two receptor subtypes; CRF receptor 1 (CRF1) and CRF receptor 2 (CRF2)(14).

Several evidences have revealed inhibitory effects of CRF on food intake (15, 16). It has been shown that intracerebroventricular (ICV) administration of CRF inhibits food intake in both mammals and chicks (17, 18). Saito et al (2005) indicated that the inhibitory effect of ghrelin on food intake was mediated by CRF in neonatal chicks (19).

Besides reported anorexic effects of CRF, none is known about the CRF involvement in anorexic effects of LPS in birds. Thus, the present study was conducted to evaluate the effect of ICV injection of Astressin as a nonselective CRF receptor antagonist on anorexic effects of LPS in chicks.

Results

Food intake response to central LPS

Time-course of chick’s food intake injected ICV with different doses of LPS is presented in Fig 1. Cumulative food intake started to decrease the appetite of chicks treated with LPS (100 and 1000 ng) 30 min post injection and this suppression continued strongly, so that chicks almost did not consume food until the end of the experiment. However, this suppression was statistically significant from 120 min post injection and thereafter. The central effects of astressin (20μg) and astressin co-injected with LPS (100 ng) on cumulative food intake of birds are represented in Figure 2. Food intake was not decreased by LPS plus astressin (except 240 min post injection), while it was significantly decreased by LPS alone compared to the control 60 to 240 min after injection. Also, astressin or LPS plus astressin, significantly increased food intake compared to the LPS group. All of these results show that anorexia induced by LPS is attenuated by the blockage of CRF receptors.

**Food intake response to peripheral LPS**

Figure 3 shows the cumulative food intake of birds injected IP with different doses (10, 100 and 200 μg) of LPS. Food intake tended to decrease by all levels of LPS as a dose dependent manner. However, in chicks with 200 μg LPS, food intake was strongly suppressed so that the birds did not eat nearly until the end of the experiment. However, this suppression was statistically significant from 120 min post injection and thereafter. The anorexia induced by IP injection of LPS was not attenuated by central astressin (both LPS and LPS plus astressin treated groups showed decreased food intake, while there was no significant
Discussion

In this study we have shown that peripheral and central administration of LPS could strongly diminish the neonatal chicks’ food consumption. The anorexic effects were initiated 30 min after LPS injection and enlarged with increasing doses (Figs 1 and 3). LPS from gram-negative bacterial cell walls are major promoters of the APR and reduced food intake in animals (20). In mammals, many of the physiological effects of LPS via acting on its recognition receptor toll like receptor 4 are mediated by pro-inflammatory cytokines, like interleukin (IL)-1, IL-6 and TNF-α which are released from activated cells of monocyte/macrophage lineage (21-24). Thus, Pro-inflammatory cytokines are major endogenous mediators of the acute illness anorexia. These cytokines activate cyclooxygenase 2 (COX2), an enzyme that facilitates the metabolism of arachidonic acid to prostaglandin (PG) E2 (25). In chickens, in agreement with our results, IP and ICV injections of LPS have been demonstrated to induce hyperthermia and anorexia and to increase corticosterone (26, 27). PGs have also been demonstrated to be involved in LPS-induced hyperthermia and anorexia in chickens (27). Chickens were also injected with indomethacin (a COX2 inhibitor), peripherally or centrally following a challenge with IP injection of LPS. Pretreatment with indomethacin (injected IP but not ICV) significantly attenuated the LPS-induced anorexia (27). In addition, intravenous injection of LPS has been reported to increase plasma PGE2 concentrations in chickens (28). As it was mentioned before, we also investigated the effect of the blockade of CRF receptors by Astressin on anorexia induced by LPS. The results showed that centrally (not peripherally) LPS-induced anorexia is attenuated when the CRF receptors are blocked (Figs 2 and 4). Consistent with this result, it has been demonstrated in chicks that IL-1 and 3 activate stress axis, the key pathway for prostaglandin-induced fever, sickness behavior, and anorexia (29-31). In mammals, both CRF and cortisol influence the central mechanisms involved in the regulation of food intake (32). In chicks, several lines of evidence have shown that many anorectic agents exert their effects via CRF neurons. Indeed, the anorexigenic effects of ghrelin, glucagon like peptide -1, α-melanocyte stimulating hormone, vasoactive intestinal peptide, pituitary adenylate cyclase-activated peptide, glucagon, and cholecystokinin (19, 33-37), are mediated by CRF. Although, mechanisms underlying LPS induced anorexia mediated by CRF is unknown in chicks, there are some indications.

Figure 4
Cumulative food intake following IP injection of either 0 or 200 μg LPS followed by ICV injection of 0 or 20 μg Astressin 90 min later in chicks. Values correspond to mean ± S.E.M.

# p < 0.05 compared to Astressin group
of this mechanism to be present in mammals. It has been reported that LPS induces the expression of CRF and prostaglandin E2 receptor 4 (EP4), and activates CRF neurons in the rat PVN (10, 38, 39). Pro-inflammatory cytokines may directly activate CRF neurons within PVN (40). Peripheral injections of LPS or IL-1β increase COX-2 and microsomal Prostaglandin E synthase-1 expression in blood brain barrier endothelial cells (41-43). PGE2 may directly act on its receptors, EP4 within PVN to release CRF (44). Evidences indicate that PGE2 released in response to LPS (and probably pro-inflammatory cytokines) may also act on serotonergic neurons to elicit anorexia. These evidences suggest that serotonergic neurons expressing EP3 receptors might be activated by PGE2 and project to areas of the hindbrain and forebrain that are involved in the control of food intake (45, 46). Pre-treatment with NS-398, a COX-2 inhibitor, reduced or eliminated LPS-induced c-Fos expression in several brain areas including the raphe complex, a source of serotonergic neurons (47, 48). Serotonergic neurons via their 2C receptors may act on PVN to release CRF (48). Recently, Zendehdel et al reported that pre-treatment with a 2C serotonin receptor antagonist significantly attenuated food intake suppression caused by LPS in chickens (49).

In this study, IP injection of LPS followed by ICV injection of Astressin couldn’t attenuate LPS-induced anorexia effects. This discrepancy may be attributed to the difference in peripheral and central pathways of LPS action. In agreement to this, Johnson et al showed that central injection of LPS increases corticosterone plasma levels more than peripheral LPS, indicating that more CRF is released by central LPS (26).

In conclusion, current study revealed that both central and peripheral LPS strongly suppress food intake in chicks 30 min post injection and thereafter. The required amount of LPS for central suppression was about 1000 times lower than that required for peripheral suppression. Our results also identified that the CRF receptors are involved in the anorexic effect of central LPS in chicks. CRF has been shown to be a food intake inhibitor in chicks and many anorexigenic factors act through the CRF pathway in chicks. However, further studies are needed to clarify the CRF receptor subtypes involved in the above mentioned pathway in chicks.

**Material and methods**

**Animals**

One-day-old Ross broiler chicks were purchased from a local hatchery (Mahan Chicken Meat Production Complex, Kerman, Iran). All birds were given free access to a commercial feed and water and continuous lighting. The temperature and relative humidity of the animal cage were maintained at 30 ± 1°C and 50 ± 5%, respectively. Animals were placed in individual cages, one day before the experiment. All efforts were made to decrease distress. The principles of working with animals were based on the recommendations of the ethics committee of Kerman University of Medical Sciences, Kerman.

**Drugs**

LPS from Salmonella typhimurium (Sigma & Aldrich, USA) and Astressin (Tocris Bioscience, UK), a nonselective CRF antagonist, dissolved in sterile 0.85% NaCl plus 0.1% Evans Blue (Sigma & Aldrich, USA). Control animals received drug vehicle. All drugs were freshly prepared on each experimental day.

**Microinjections**

ICV injection was performed according to Davis et al method (50). Briefly, the head of the chick was inserted in a straining device which positioned a hole in a plate overlying the skull immediately over the right lateral ventricle. A microsyringe was then inserted into the right lateral ventricle through the hole and infusions were delivered in a total injection volume of 10μl. This method requires no anesthesia and stress level of birds is insignificant (19, 51). At the end of each behavioral test, the animals were killed with intracardiac injection of sodium thiopental and their brain was removed. Validation of drug injection was verified by the presence of Evans blue in the right lateral ventricle. If an injection was not fixed in the correct location, the chicks’ data were omitted from the analysis.

**Experimental procedure**

This study was designed in four experiments. In experiment 1, chicks were given ICV injection of LPS at 0, 10, 100 and 1000 ng. Experiment 2 was conducted to determine the central effects of Astressin, as a CRF receptor antagonist, on LPS-induced change in chicks’ food intake. Thus, the birds received ICV injection of LPS at 0 and 100 ng, Astressin at 20 μg and Astressin (20 μg) plus LPS (100 ng). In experiment 3, animals were given an intraperitoneal (IP) injection of LPS at 0, 10, 100 and 200 μg. Experiment 4 was similar to experiment 2 except that the chicks were given IP injection of either 0 or 200 μg LPS, then, 90 min later, they received ICV administration of either 0 or 20 μg Astressin. In all experiments, 6-day-old chicks were deprived of food for 3 h prior to injections in order to motivate and coordinate feeding. Cumulative food intake was measured at 30 to 240 min post injection. 9-12 chicks were used for each experimental group.

**Data analysis**

Data was presented as means ± SEM. The results were evaluated statistically using ANOVA (IBM*SPSS statistics* version 23) followed by a post hoc Duncan’s new multiple rang test (MRT). Differences were considered statistically significant when p < 0.05.

ABSTRACT

Snake venom is a complex mixture of different compounds which have potential pharmacological properties and may affect mesenchymal stem cells (MSCs). In this study we investigate the effects of two Iranian vipers; *vipera albicornuta* and *vipera latifi i* crude venoms on the viability of MSCs in vivo and in vitro. The cells in in vitro tests were treated with different concentrations (1, 2, 3, 4 and 5 μg/100μl) of mentioned venoms for 24, 48 and 72 hours. The cells in in vivo experiment only were treated with *v. Latifi i* venom at the concentration of 1μg/100μl and time intervals as in vitro tests. The cell viability in in vitro experiment was assessed using MTT assay. The results of in vitro experiments showed that maximum cell viability was observed at concentrations of 1 and 2 μg/100μl of *v. albicornuta* and *v. latifi i* venoms after 48 and 72 hours, respectively. The results of in vivo experiment showed that the cells treated with *v. Latifi i* venom for 72 hours in situ have the highest proliferation rate after passages three, four and five in comparison to control. The results of this study showed that the *v. albicornuta* and *v. latifi i* venoms can affect the confluence and viability of the MSCs.

Introduction

MSCs are known as self-renewing, multipotent progenitor cells, capable of differentiating into mesodermal lineages, including adipocytes, osteocytes, and chondrocytes (1). They were initially discovered in bone marrow (2) and then were isolated from almost every type of tissue (3,4) and because of their ease of isolation and ex vivo expansion, MSCs are known as promising therapeutic tools for the treatment of various diseases (5). In human medicine, MSCs are used for their anti-inflammatory properties and ability to aid in tissue and bone regeneration (6). Due to the advantages of MSCs compared to other cells for therapeutic applications, the techniques for MSC proliferation and differentiation are needed. In stem cell therapy, extensive use of synthetic substances, recombinant cytokines and growth factors could be a contributing factor in increased side effects and toxicity. Therefore, search for alternative natural products to be used as growth factors and other effective components in stem cell therapy is important (7). Venomous animals possess a novel source of pharmacologically effective substances including metallic cations, carbohydrates, nucleosides, biogenic amines and lipids and other components in their venoms (8,9). Among them, snake venoms are a cocktail of diverse molecules, biologically active compounds, and a combination of many different proteins and enzymes with a variety of pharmacological effects and valuable therapeutic potential (8,10,11). A number of studies have revealed the ability for snake venom toxins to be used as a diagnostic tool, and that they possess possible therapeutic properties and great potential for the development of lead compounds for new drugs (12,13). Previous studies have reported that nerve growth factors (NGFs) isolated from Chinese cobra snake venom, exert potential effects on the chondrogenic differentiation of bone marrow MSCs (BMSCs) and cartilage regeneration in vitro and in vivo (14,15). Direct addition of the snake venom phospholipase A2 is effective in the enhancement of the PMA-induced HL-60 cell differentiation to macrophages (16). Surveys such as that conducted by Liu et al., showed that vascular endothelial growth factor (VEGF) dependent mechanisms, stimulate the balance between osteoblast and adipocyte differentiation in BMSCs (17).

Gasparotto and colleagues used a new fibrin sealant (FS), derived from Crotalus durissus terrificus snake venom to evaluate the in vitro growth and cell viability of MSCs (25). The new fibrin sealant was a three-dimensional scaffold that maintained cells survival without promoting their differentiation (18). Kouchesfahani et al., showed that applying honey bee venom (BV), which consisted of mellitin, phospholipase A2, apamin and other bioactive ingredients, with retinoic acid has an effect on mouse P19 cell proliferation and differentiation to neurons (19).

The objective of this research is to determine the possible effects of two Iranian snakes, *V. albicornuta* (zanjani) and *V. latifi i* (latifi i) venoms on the viability rate of MSCs derived from rat bone marrow in vitro and in vivo.

Results

Vipera Latifi i venom effect on viability of BMSCs in vitro

BMSCs were treated with various concentrations of *V. latifi i* venom (1, 2, 3, 4, 5 μg/100 μl) in vitro, and

the effect on cell viability was analyzed using the MTT assay. The maximum cell viability and proliferation at different concentrations was observed after 72 hours (Figure 1). The viability differences between 24 and 72 hours was significant ($p = 0.015$) at concentration of 2 μg/100μl, while it was not as significant between 48 and 72 hours. In addition, viability differences between different concentrations was not significant (Figure 1).

Vipera albicornuta (zanjani) venom effect on viability of BMSCs in vitro

BMSCs were treated with various concentrations of *v. albicornuta (zanjani)* venom (1, 2, 3, 4, 5 μg/100μl) *in vitro*, and MTT assay and Post Hoc test were used to evaluate the viability of BMS cells. The maximum cell viability at different concentrations was observed after 48 hours (Figure 2). At concentration of 1 μg/100μl the viability differences between 24 and 48 and also between 48 and 72 hours was significant ($p = 0.046$) and ($p = 0.014$), respectively. At concentration of 3 μg/100μl the viability differences only between 48 and 72 hours was significant ($p = 0.039$) (Figure 2).

The measured viability showed that among different concentrations there is no significant differences at 24, 48 and 72 hours (Figure 2).

Comparison between vipera latifii and vipera albicornuta (zanjani) snake venom effects on viability of BMSCs at 72 hours

At concentration of 2 and 3μg/100μl the viability differences between *v. latifii* and *v. albicornuta* venom was significant ($p = 0.004$) and ($p = 0.014$), respectively (Figure 3).

Preliminary results of the effect of Vipera Latifii venom on rat bone marrow

The quality of extracted MSCs were evaluated by the doubling time in cell culture. Cells were grown to 80 to 90% confluency as determined by visual assessment using phase contrast microscopy every 24 hours. Cells were harvested and subcultured at 1:2 ratio. The results showed that the cells treated with venom for 72 hours *in situ* have the highest proliferation rate after passages three, four and five in comparison to control, while cells treated for 24 hours with venom *in situ* were growing more slowly in comparison to control (Figure 4).

The cells at different passages in control group were reached to confluency in relatively the same time interval, while the cells in treatment groups showed higher rate of proliferation and growth. As shown in figure 4, the rate of cell proliferation increased after third passage at 48 and 72 hours.

Discussion

We sought to evaluate the effects of two Iranian viper snake venoms on MSCs and this study demonstrated that these venoms are able to affect cell viability *in vitro* and *in vivo*. The results of this study showed that MSCs cells viability increased after incubation
in vitro with media containing venoms. For *v. latifii* snake venom, the highest viability was observed after 72 hours incubation at concentration of 2 μg/100 μl venom with 63% increased compare to control, and the lowest viability was after 24 hours (Figure 1). For *v. albicornuta (zanjani)* snake venom, the maximum viability occurred at 48 hours of treatment at concentration of 1 μg/100 μl venom with 40% increased compared to control (Figure 2). The observed effects seems to be more dependent to time than concentration as there was not significant differences among different concentrations at 24, 48 and 72 hours.
It was found that in vivo, the doubling rate of the cells after being treated with latifi venom was the highest in the 72 hours treatment group (Figure 4). Considering the effects of endogenous factors and injected venom interactions, MSC viability may differ from that of in vitro. It is important to recognize that this study is the first study of its kind to investigate the effects of snake venom on stem cells in situ. Although the exact mechanisms by which these venoms affected the viability of MSCs are not clear, several points can be considered in an effort to explain this phenomenon. For example, in 2009, Chen and colleagues showed that initial expansion of MSC cells is influenced by the culture parameters such as media, cell density and even culture flasks (20). Therefore one possible conclusion is that any factors which change the media composition like venoms, may can affect cell viability. It has been shown that MSCs behavior such as tissue repair, immunomodulation, differentiation and proliferation may be influenced by their secretion products (paracrine factors) including soluble factors and extracellular vehicles (EVs) which participate in formation of a favorable microenvironment (21). Some of EV’s are secreted after cell apoptosis, some during stress or metabolic changes, and some are secreted continuously (22–26). It is possible that after dissolving within this specific microenvironment, the individual components of the complex venoms undergo a biochemical change which could result in an alteration of MSC viability. Furthermore, growth factors are often added to stimulate the differentiation and improve cell proliferation. Several reports indicate that all snake venoms are a rich source of growth factors such as NGF (27). In 2017, Lu and colleagues showed that NGF from venom of Chinese cobra which induced the BMSCs to differentiation and improve cell proliferation. Several reports indicate that all snake venoms are a rich source of growth factors such as NGF (27). In 2017, Lu and colleagues showed that NGF from venom of Chinese cobra which induced the BMSCs to differentiate into the chondrogenic lineage in vitro and in vivo (14). Therefore, another possibility can be that these snake venoms possess several growth factors that stimulate MSCs proliferation and viability.

In 2002 Liu et al., reported that bee venom (BV) inhibited cell proliferation and induced K173SM2 mouse melanoma cells differentiation in vitro. In 2015, Jung et al. reported that bee venom has neuroprotective effects against rotenone-induced cell death in NSC34 motor neuron cells and pre-treatment of these cells with bee venom significantly enhanced cell viability. In 2010, Kouchesfahani and colleagues reported that snake venom Lys49 PLA2 homologues at lower concentrations, caused cell proliferation (29). To the best of authors' knowledge, no systematic publication exists to address the exact presence of PLA2 in vipera latifi and vipera albicornuta snake venoms. Although, it has been explored in prior studies that (PLA2) is one of the most abundant protein families found in vipera venoms (8,30). This suggest that possible (PLA2) of vipera latifi and vipera albicornuta venom treated the viability of rat MSCs the way the bee venom (PLA2) treated.

This is the first study investigating the effect of vipera snake venoms on MSCs in vitro and in vivo. In this study, direct injection of venom into bone marrow raised this possibility that venom may react to bone marrow composition in situ, that in turn affected the rate of cell growth and viability. The present results showed that the cells that were treated with vipera latifi venom in bone marrow for 72 hours can grow noticeably faster when they transfer to normal culture media.

It is beyond the scope of this study to examine the effect of venom peptide and enzyme compounds separately on MSCs. It is undisputable that venoms have varieties of pharmacologically active compounds and therefore various biological effects. The venoms somehow affect the viability of MSC and altered the survival and proliferation rate of rat bone marrow MSCs in vitro and in vivo. However, their fundamental and detailed molecular mechanisms is not clear. In addition, the bone marrow can be considered as a suitable model to investigate venom and similar compound effects on viability of stem cells in situ, however more research on this topic needs to be undertaken to explore the effect of individual components of these venoms and their mechanisms.

Material and methods

Chemicals

All chemicals including: Dulbecco’s Modified Eagle’s Medium (DMEM), penicillin/streptomycin and amphotericin B, phosphate-buffered saline (PBS), fetal bovine serum (FBS), chloroform, ketamine, xylazine and, MTT powder were obtained from Sigma (Germany) unless otherwise stated. Reagents were prepared and stored according to the manufacturer’s guidelines. Non chemical material were; insulin syringes, 75 cm² culture flasks and, 96-well plates.

Venoms

The vipera albicornuta and vipera latifi venoms were generously provided by Exhibition of Animal Sciences Development,
**Animals**

Five Sprague-Dawley female rats (1-2 month old) were purchased from Animal House of Mashhad University of Medical Sciences. The rats were housed in the Animal Center of Faculty of Veterinary Medicine in a standard animal facility and maintained on a 12-hour light/dark cycle and were allowed food and water ad libitum. It should be noted that all animal experiments were approved by Animal Care and Use Committee of Ferdowsi University of Mashhad.

**Isolation and culture of MSCs**

One rat was succumbed with chloroform, its legs cleaned with warm water and shaved, afterwards the skin was swabbed with 70% alcohol. With two small surgical incisions, its two femurs and tibias were removed and transferred to the laminar hood. The muscles around the bones were removed, and washed 3-5 times with 1x phosphate-buffered saline (PBS). Bones were sterilized with 70% ethanol, washed by Dulbecco’s Modified Eagle’s Medium (DMEM) and epiphysis of the bone was separated by scissors. The bone marrows were then flushed out using DMEM, supplemented with 10% (v/v) FBS, 1% penicillin/streptomycin and 0.1% Amphotericin B. The medium was flushed into the bone using an insulin syringe. Cell suspension was collected and centrifugated at 200g for 5 minutes. Supernatant was removed and cell pellet was re-suspended with 1ml of culture medium. Finally, the released cells were collected into 75 cm2 culture flasks with 10 ml DMEM culture medium. The cells cultures were maintained at 37°C in a humidified atmosphere of 95% air and 5% CO2. Cells were allowed to attach for 4-5 days, the non-adherent cell population was removed and the culture medium was replaced with fresh pre-warmed culture medium. MSCs were attached to the bottom of the flask, due to their adhesion properties.

**In-vitro study design**

The cells were used after three passages, seeded into 96-well plates at a density of 0.05×10^4 cells/well. The cells were divided into six groups that included one control and five test groups. 150 μl of fresh pre-warmed culture media was added to each well of all groups. After 24 hours, the medium was aspirated and the test groups were treated with 200 μl phosphate-buffered saline (PBS) containing different concentrations (1, 2, 3, 4, and 5μg/100 μl) of v. albicornuta and v. latifi venom while only 200 μl PBS was added to the control group. After one hour venom/PBS solutions were removed and all groups prepared for MTT test. It should be noted that, the selected venom concentrations were based on our previous research (unpublished results), on determination of the LD0, LD50 and LD100 of these venoms. Based on that experiment we chose the concentrations lower than LD50.

**MTT Assay**

Cell viability was assessed via a quantitative colorimetric assay using MTT (27). Five mg MTT powder was dissolved in 1ml PBS and the solution was sterilized using 0.2 μm filter. After 24, 48 and 72 hours, 20 μl MTT solution was added to each of 96-well containing the cultured cells in the culture medium and incubated for 4 hours at 37°C. The culture medium was carefully aspirated and 150 μl DMSO solution was added to each well. Finally, the optical absorption of each well was measured using an ELISA reader at 570 nm.

**In-vivo experiments**

Three rats were anesthetized with a combination of 60 mg/kg ketamine and 6 mg/kg xylazine (IP route) and one rat used as control. The animals were kept in a dorsal recumbent position, the anterior face of their thighs shaved, and the area disinfected with 70% ethanol. For intra-femoral injection, a minor surgery under anesthesia was performed. By opening the femur skin, the greater trochanter of the proximal femur was exposed. Five hundred microliters of v. latifi venom at concentration of 1 μg/100 μl was injected into the bone marrow of the right femur by using a 22 gauge metallic needle and then the animals returned to their cages. Their food and water consumption were normal and they were in healthy condition. MSCs were extracted after 24, 48, and 72 hours from the bone marrow of these rats. The cells were counted in each passage. To determine doubling time, when the cells reached to 90% confluency, they were cultured to sixth passages.

**Statistical analysis**

The Kruskal Wallis nonparametric test was used to compare medians among groups (n=3 per group) and Dunn’s multiple comparison test was used to compare two groups in terms of viability. Values of p lower than 0.05 were considered statistically significant.

Antibacterial effect of *Lavandula stoechas* and *Origanum majorana* essential oils against *Staphylococcus aureus*, *Streptococcus agalactiae*, and *Escherichia coli*

Samira Noori, Reza Rahchamani, Javad Bayat Kohsar, Fateme Bahri Binabaj

This research examined the antimicrobial effect of *Lavandula stoechas* (lavender) and *Origanum majorana* (marjoram) essential oil against three pathogens: *Staphylococcus aureus*, *Streptococcus agalactiae*, and *Escherichia coli*. Gas chromatography-mass spectrometry (GC/MS) analysis revealed that the main components of the lavender and marjoram oils were 17-Pentatriacontene, Linalyl acetate, Eucalyptol, linalool and 3-Cyclohexene-1-ol,4-methyl-1-(1-methylethyl)-,(R)-, α-terpineol, P-cymene, respectively. Broth dilution testing was performed using autoclaved whole milk instead of broth to determine minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) of essential oils alone and in combination. In addition, time-kill assay of lavender and marjoram oils were determined in milk up to 24 h. MIC values ranged from 3.12 - 4.37% v/v and MBC between 6.25 - 8.75% v/v for the lavender. The MIC and MBC of the marjoram ranged from 0.62 - 1.87% v/v and 1.25 - 3.75% v/v, respectively. The MIC ranged from 2.5 - 5% v/v and MBC between 5 - 10% v/v for lavender + marjoram combination. In time-kill assays, the presence of lavender and marjoram oils at a sub-MIC concentration significantly reduced the bacterial population in 4, 10 and 24 h. Generally, essential oil of marjoram had greater antibacterial activity than lavender against all mastitis-causing pathogens tested and has the potential to be evaluated as an alternative or adjunct to antibiotics in the treatment of bovine mastitis.

MIC: minimum inhibitory concentration  
MBC: minimum bactericidal concentration  
GC/MS: gas chromatography/ mass spectrometry
Introduction

Treatment of bacterial diseases are often encountered problems of increase in drug resistance and side effects of conventional medication [1]. In this context, natural products have a key role in discovery of alternative drugs [2]. Secondary metabolites of medicinal and aromatic plants present key candidates for discovering antimicrobial agents to fight against numerous microbial diseases.

Essential oils (EOs) have antibacterial, anti-fungal and antiviral activity and have been studied for finding new antimicrobial compounds, alternatives to cure microbial diseases [3]. Essential oils show antibacterial effects, therefore, the study of EOs antibacterial effects against bacterial agents is justifiable [4].

Lavandula is a medicinal plant from the family of Lamiaeae which is traditionally utilized to overcome diseases [1]. Antimicrobial [1,5,6] and antioxidant [7] activities of \( L. \) stoechas EO have demonstrated in several studies.

Origanum majorana (marjoram) from the Lamiaeae family has been used in traditional and folklore medicines for many disorders of gastrointestinal, respiratory, cardiac, and nervous system. Chemical constituents such as monoterpene hydrocarbons, oxygenated monoterpenes, and phenolic compounds have been isolated from marjoram essential oil. In pharmacological studies of marjoram, antibacterial, antifungal, antiprotozoal, and antioxidant activities have been reported in modern medicine [8].

Different diseases are caused by \( S. \) aureus, \( S. \) agalactiae, and \( E. \) coli. Mastitis is a common and important disease that can be produced by all these bacteria. The main causative agents of bovine mastitis are bacteria such as \( S. \) aureus, \( S. \) agalactiae, and \( E. \) coli.

Results

Chemical composition of the essential oils

GC/MS analysis revealed that the main components of the lavender and marjoram oils were 17-Pentatriacontene (42.15%), linalyl acetate (26.82%), eucalyptol (18.87%), linalool (5.7%), and 3-Cyclohexene-1-ol,4-methyl-1-(1-methylethyl)-,(R)-(44.84%), α-terpineol (6.83%), P-cymene (6.75%), respectively. (Tables 1 and 2).

MIC and MBC

The MIC and MBC of lavender and marjoram EOs on the mastitis bacteria are shown in Table 3. Although lavender, marjoram, and marjoram + laven-

RT: Retention on HP-5MS column in minutes
der essential oils displayed antibacterial effects, marjoram oil was the most effective against the bacteria. Marjoram had the lowest MIC and MBC for the three pathogens compared to the other two essential oils.

**Bactericidal kinetics of the oils**

The bactericidal kinetics of lavender and marjoram against mastitis bacteria in milk were shown in Figures 1, 2, 3. The initial population of bacteria in the control and treatment groups for the three bacteria was approximately 6.0 log10 cfu/ml. The population of control and treatment groups for the three bacteria reached about 12 log10 cfu/ml in the control group during the 24 h incubation period. The presence of lavender and marjoram at a sub-MIC concentration significantly reduced the bacterial population to 3.59 to 4.68 log10 cfu/ml in 4, 10 and 24 h except for lavender that insignificantly decreased *E. coli* population to 5.31 log10 cfu/ml in 4 h. However, the time-kill assay and MIC and MBC experiments showed the antibacterial effect of lavender and marjoram in milk.

**Discussion**

Bovine Mastitis is an important disease in organic farms due to its prevalence and lack of efficient cures for that. There is a growing need for organic antibacterials that can be used in dairy farms. A growing need is for organic antibacterials, which can be used in organic dairy farms, that do not emerge antibiotic resistance. It seems that the possibility of drug resistance decreases when a dairy herd transits from conventional to organic status [13].

The broth dilution method is frequently used to study antimicrobial efficacy of different essential oils [14], but milk was used instead of broth in the present study to mimic the udder environment. Moreover, hydrophobic properties of lipids and other lipophilic molecules of milk may reduce the antibacterial activity of essential oils on mastitis-causing bacteria [15].

This work has demonstrated that the major components of the lavender EO were 17-Pentatriacontene, linalyl acetate, eucalyptol, and linalool. Main components of lavender were reported to be fenchone, camphor, and terpineol from Morocco [1] and fenchone, eucalyptol, and camphor from Spain [7]. Ashghari et al. reported camphor, 1,8 cineol, linalool, borneol and Mashak et al. found 1,8 cineol, borneol, camphor, linalool as main components of lavender EO in Iran [16,17]. Some of the aforementioned compounds were absent in our study that was in agreement with Carrasco et al. who declared that the main components of lavender had high variability even in the common constituents, i.e., camphor (0–49%) and fenchone (0–66%) [7]. This shows that study of biochemotypes existing in the different locations is important.

In the present study, main constituents of marjoram were 3-cyclohexene-1-ol, 4-methyl-1- (1-methylethyl)-(R)-, P-cymene and linalool. Hajlaoui et al. reported that the Tunisian marjoram EO mainly consisted of terpinene-4-ol, followed by cis-sabinene hydrate, g-terpinene, and P-cymene [18]. The main components of the Venezuelan Andes marjoram EO were reported cis-sabinene hydrate, terpinene-4-ol, g-terpinene, a-terpineol, trans-sabinene hydrate, linalool acetate and a-terpinene [19]. In a study, terpinolene-4-ol, g-terpinene, and a-terpineol were reported as the main constituents of marjoram EO in Iran [20]. Factors such as species, location of herb, growth stages, climatic conditions, distillation conditions, and the analyzed part of the plant are involved in variation of lavender and marjoram EO components [18].

Lavender and marjoram oil had antibacterial activity against the bacteria in the present study which are prevalent bacteria on organic farms [13]. Antibacterial effects of Lavender and marjoram oil has been reported against *E. coli* [1,18,19] and *S. aureus* [1,8,21,22]. Thus we hypothesized that lavender and marjoram oil are effective antibacterial agents against pathogens causing bovine mastitis. In the current study, we showed that lavender and marjoram oil could kill all tested bacteria. The MIC of marjoram oil for all tested bacteria obtained was lower than that of lavender and lavender + marjoram. In general, marjoram oil exhibited stronger activity than did lavender and lavender + marjoram oil. In agreement with our results, Dadalioglu and Evrendilek reported that Spanish lavender essential oils had a weak antibacterial effect [5].

In this research, MIC and MBC of lavender were 3.12% and 6.25% for *E. coli* and 4.37% and 8.75% for *S. aureus*, respectively. Also, MIC and MBC of marjoram were 0.62% and 1.25% for *E. coli* and 1.56% and 3.2% for *S. aureus*, respectively. Different values have
reported for MIC and MBC of lavender and marjoram. Bouyahya et al. and Gayatri et al. obtained MIC values of 0.5% and 0.25% against *E. coli* for lavender and 0.5-2% and 0.5% against *S. aureus*, respectively [1,23]. MIC and MBC values of 7.8% and 15.6% against *E. coli* and 1.9% and 7.8% against *S. aureus* for marjoram have reported, respectively [18]. In another study, MBC value of marjoram for *S. aureus* was obtained 0.25% v/v [24]. The different values of MIC and MBC in various studies might be because of the variable components of EOs and susceptibility of strain.

Antimicrobial effects of EO is not due to one specific mechanism because there are several different chemical groups in the structure of EO. Hydrophobicity of essential oils or their components helps them to target the cell membranes of bacteria that contain lipid. This property increases the permeability of membranes, thus contents of cell leak [12]. An outer membrane is present in Gram-negative bacteria that prevent penetration of essential oils into cells. Moreover, periplasmic extracellular enzymes might deactivate anti-microbial components of essential oil [25]. Thus we expected that essential oils to be more effective against Gram-positive *S. agalactiae* and *S. aureus* than Gram-negative *E. coli* but, MIC and MBC of *S. aureus* and *S. agalactiae* was higher than *E. coli* in all treatments except marjoram that MIC and MBC of *S. aureus* were lower than *E. coli*. Our results from the MIC and MBC indicated that the most sensitive microorganism against lavender and lavender + marjoram was *E. coli* and against marjoram was *S. aureus*. In agreement with our findings, in a previous study, MIC of lavender EO was higher against *S. aureus* than *E. coli* [1]. Similar to our finding, Tunisian marjoram EO showed a higher MIC and MBC against *E. coli* than *S. aureus* [18]. In contrast, MIC of marjoram against *S. aureus* was one fold upper than that of *E. coli* [26]. Essential oils of Plant potentially have several antimicrobial constituents. Comparing the findings of different researches is difficult because they use different bacterial strains, test methods, and source of antimicrobial samples. The great variability of composition of the essential oil can be attributed to the extraction method of the EO, geographical region, variety, and plant age [27].

We further carried out a time-kill curve set of tests, to ascertain time of inhibition or killing these pathogens. Lavender and marjoram oil displayed a bacteriostatic effect in the first 2 h and bactericidal effect between 4 and 24 h. Lavender and marjoram oil at sub-MIC caused a ~2.0 log10 cfu/ml reduction of *S. aureus*, *S. agalactiae* and *E. coli* within 24 h (Figures 1, 2, and 3).

Mullen et al. reported the antimicrobial effect of an herbal intra-mammary product on mastitis-causing bacteria and declared that the antibacterial effect of the formula might be due to *Thymus vulgaris* (thyme) [28].

In conclusion, essential oil of marjoram had greater antibacterial activity than lavender on the mastitis-causing bacteria (*S. aureus*, *S. agalactiae*, and *E. coli*). Results of this research showed that marjoram EO might be effective as an alternative or adjunct to antibiotic therapy to control bovine mastitis. However, further in vivo tests are needed to evaluate the efficiency on treatment of bovine mastitis and potential side effects on the mammary gland tissue.

**Material and methods**

**Essential oils**

Lavender and marjoram EO were purchased from Barij Es-
Analysis of Chemical Composition of the Essential Oils

GC/MS analysis was performed using an Agilent 7890B gas chromatograph coupled to a mass detector (Model 5977A, Agilent Technologies, USA) and a HP-5MS capillary column (phenyl methyl siloxane, 30 m × 0.25 mm ID 0.25 um, Agilent Technologies). The temperature of injector was 270°C, and the temperature of oven was raised from 60°C (0 min) to 200°C by a rate of 5°C /min. The analysis was performed using helium as a carrier gas while the flow rate was adjusted to 1 mL/min and injection volume (1μl). The interface temperature was set at 280°C and mass range was 35 - 500 m/z.

Bacterial strain

The activity of the EOs was tested toward three major mastitis bacteria including Staphylococcus aureus (ATCC 9144), Streptococcus agalactiae (ATCC 13813), and Escherichia coli (ATCC 25922). These bacteria were obtained as a lyophilized culture from Persian Type Culture Collection, Tehran, Iran (PTCC). The lyophilized cultures were grown twice in tubes containing 10 ml of Tryptic Soy Broth (TSB) (Biolife, Milano, Italy) at 37°C for 18 - 20 h (overnight). Afterwards, cultures were diluted with sterile glycerin (1:5) and stored in micro tubes at - 20°C for our research. To obtain fresh bacteria, it was cultured twice in TSB at 37°C for 20 h followed by streaking on Tryptic Soy Agar (TSA) (Biolife, Milano, Italy) slants and incubation under the same conditions. The cultures were stored at 4°C and sub-cultured monthly [29].

Preparation of Inoculum

Cells were transferred from working cultures to tubes of TSB and incubated at 35 ºC for 18 h to obtain Bacterial inoculum. Next subcultures were performed and incubated at 35°C for 18 h. A spectrophotometer (Libra S12, Biochrom Ltd., Cambridge, London) was used to set the bacterial broth cultures to optical density (OD) of 0.1 at 600 nm, and a cell concentration of 2.4 × 10^10 for S. aureus and 1.64 × 10^11 for S. agalactiae were obtained. The number of cells in the suspensions was estimated by duplicate plating from tenfold serial dilutions on TSA and counting the colonies after 24 h incubation at 35°C [29]. The working inoculum was prepared by 1: 500 dilutions of the primary inoculum.

Milk Preparation

Milk without antibiotic residues was collected and then autoclaved for 15 min at 121°C.

Determination of MIC and MBC

Essential oils were diluted (1:1) in dimethylsulphoxide (DMSO, Sigma, Germany) and filter sterilized. This dilution was used in the antibacterial analysis. Herbal oils alone or in combination (1:1) were tested using a modified protocol for broth dilution testing according to the Clinical & Laboratory Standards Institute (CLSI) instruction [30]. Whole autoclaved milk was used as the growth medium. Twofold serial dilutions of the oil dilution were performed for the determination of MIC. Treatments were added to milk and were vortexed. Total volume of test vials was 1 mL. Then 100 μl of inoculum of each bacterium was inoculated into each tube. The vials again were vortexed and incubated at 37°C for 24 h. Eight 10-fold dilutions were prepared using sterile 0.85% saline solution. The samples were plated on a TSA plate and incubated at 37°C for 24 h for enumeration of inoculated bacteria. The MBC was defined as the lowest concentration without visible growth and subsequent concentration was taken as the MIC. Milk was cultured alone as a negative control to ensure that autoclaving was successful. Milk + bacteria were included as positive control to document growth of bacteria in milk. Vehicle control was DMSO to evaluate possible antibacterial effect of this solvent.

The occurrence of synergism/antagonism in antibacterial action among the EOs of lavender and marjoram was evaluated against mastitis pathogens. For this purpose, the essential oils were mixed volume to volume (1:1).

Bactericidal kinetics of the oils

Sterile milk was inoculated the sub-MIC of EOs with each pathogen in the same way as the above MIC tests. Control samples were inoculated milk without EO. Bacterial populations were counted at 1, 2, 4, 10, and 24 h of incubation at 37°C for 24 h on TSA plates. Each treatment was done in duplicate. Time-kill curves were constructed by plotting log10 cfu/ml against time (hour).

Statistical analysis

All tests were carried out in duplicate. The data were evaluated by analysis of variance (ANOVA) and the Tukey’s test using the SPSS 18 statistical software (IBM Corp., Armonk, NY, USA) at p < 0.05 statistical level.

ABSTRACT
An 8-week feeding experiment was conducted to investigate the inclusion potential of five levels of Calotropis persica seed powder (CSP) (0, 10, 20, 30, 40 and 50 g/kg of the basal diet) in rainbow trout (Oncorhynchus mykiss) diet, in a completely randomized design. To perform the test, 3600 fries (11.5 ± 3.64 g) were treated for 56 days. According to the results, the increase in milkweed seed powder up to 40 g/kg, resulted in a significant increase in specific growth rate and intestinal lactic acid bacteria count compared to the control (p < 0.05). The best results of survival rate, feed conversion ratio, hepatosomatic and gastro-somatic indices were achieved in the treatments receiving 20, 30, 40, and 50 g/kg CSP (p < 0.05). Antibacterial activity of skin mucus, lysozyme and alkaline phosphatase showed the highest level in the 40 g/kg treatment (p < 0.05). Based on the results, the inclusion of 40 g/kg milkweed seed powder caused positive health effects and could be a suitable herbal feed additive in the rainbow trout diet.

Keywords
Calotropis persica, growth, immunity, gut microbiota, Oncorhynchus mykiss

Abbreviations
CSP: Calotropis persica seed powder
FCR: feed conversion ratio
HIS: hepatosomatic index
GaSI: gastro-somatic index
SGR: specific growth rate
ALP: alkaline phosphatase
PTCC: Persian Type Culture Collection
RaRBC: rabbit red blood cells
OD: optical density
CFU: colony forming unit
TVC: total viable count
LAB: lactic acid bacteria
ANOVA: analysis of variance
Introduction

Despite the positive effects of hormones, antibiotics, vitamins and several other chemicals in the aquaculture industry, their residual and other side effects restrict their use in aquaculture operations (1). Thus, various alternatives have been proposed, including the use of probiotics, prebiotics, synbiotics, herbal medicines, etc. For reasons such as the availability, affordability and accessibility of herbal medicines, they have attracted much attention to aquaculture research, due to the advantages of herbal additives on growth performance, immunity, and appetite promotion (2), inhibitory and/or stimulatory effects in reproduction (3) and their antimicrobial properties (4). The review of the current literature indicates that there is a lot of information about the application of famous herbs such as garlic, rosemary, onion, peppermint, etc. (5) in aquaculture, while other plants with medicinal properties such as milkweed (Calotropis spp.) are less studied.

Giant milkweed (Calotropis persica) is a wild plant belonging to the Asclepiadaceae family (6). It grows in dry habitats (150–1000 mm precipitation per year) (7) and is native of West, North and East Africa, Arabian Peninsula, Southern Asia, and Indochina up to Malaysia (8). The various components of Calotropis spp. have different medical and industrial properties reported in literature (9–14). The plant is a rich source of many bioactive compounds which are of medicinal and industrial importance, for example Mohanraj et al, 2009 showed that the leaf extracts of C. procera have anti-HIV-1 and antimicrobial activity. Other researchers used the latex protein of C. procera to prevent the septic shock due to lethal infection by Salmonella enterica (9). Also, the antifungal properties of the C. gigantea extract are used to treat Fusarium mangiferae and floral malformation in mango (12). For industrial applications of C. gigantea, oil extraction from seed and biodiesel production can be mentioned (11).

Some researchers have shown that the antibacterial, anti-fungal and anti-viral properties of different parts of Calotropis Sp. can be usefully exploited in aquaculture. Recently, C. persica ethyl acetate leaf extract was used against shrimp and fish pathogens. Results showed that the extract efficaciously suppressed the bacterial pathogens Pseudomonas aeruginosa, Vibrio harveyi and Aeromonas hydrophila; the fungi Fusarium Sp., and the virus causing the white Spot Syndrome (WSS).

Although previous studies have examined the phytochemical power of different parts of the plant such as leaves, roots, shoots, flowers, fruits and latex, there is a lack of information regarding C. persica seed application. Therefore, this study aimed at investigating the effects of C. persica seed powder on growth performance, skin mucus immunity, antibacterial activity and gut microbiota, of rainbow trout (Oncorhynchus mykiss).

Results

Growth performance

The results of growth performance, survival rate and physiological parameters of O. mykiss at the end of the 56 days experiment are shown in Table 1. The results revealed that the dietary administration of different levels of CSP significantly improved SGR, FCR, HSI and survival rate compared to the control (p < 0.05). The statistical analysis of the results also

SGR: specific growth rate; FCR: Feed conversion ratio; HSI: hepato-somatic index; GaSI: gastero-somatic index C. Persica Seed Powder (CSP)
indicate that, during the trial, the incremental trend in GaSI paralleled the amount of CSP in the diet. On the other hand, SGR and HSI decreased significantly at 50 g/kg CSP level of inclusion in the diet. \((p < 0.05)\). Furthermore, the least FCR was observed in fish receiving 20 g/kg CSP \((p < 0.05)\).

**Skin mucus immunological parameters**

Evaluation of the skin mucus parameters (lysozyme activity, ALP activity and dissolved protein content) showed that dietary administration of CSP at any level of inclusion, significantly improved lysozyme activity and ALP activity and dissolved protein compared to the control diet group (Table 2) \((p < 0.05)\).

**Skin mucus antibacterial activity**

The skin mucus of rainbow trout \((O. mykiss)\) showed significant antibacterial activity \((p < 0.05)\) against \(Y. ruckeri\), \(A. hydrophila\), \(S. iniae\), \(S. faecium\), and \(M. luteus\) in all treatments as shown in Figure 1. The highest growth inhibition zone for all tested bacteria was observed in the skin mucus of fish receiving 40 g/kg CSP for 56 days \((p < 0.05)\). The results also showed that the highest and lowest antibacterial activity of skin mucus was observed in \(A. hydrophila\) and \(S. faecium\), respectively \((p < 0.05)\).

**Discussion**

In recent decades, special attention has been paid to the role of intestinal bacteria regarding the regulation of growth and reproduction in aquatic animals \((15)\). The bacterial communities in the gastrointestinal tract increase the digestibility of proteins, lipids and carbohydrates of the diet by partaking in digestive enzymes (amylase, protease and lipase) secretion \((16)\). LAB are among the main beneficial gut bacteria, and include more than 50 species. These bacteria use carbohydrates as energy and produce lactic acid \((16, 17)\). Some indigestible feed ingredients such as fibers could stimulate lactic acid bacteria propagation and play symbiotic roles \((18)\).

In this study, the inclusion of CSP in the diet of rainbow trout, brought about a significant improvement in growth performance, survival rate and nutritional indices. The findings were similar to that reported by Jayapracas et al. \((1997)\), who investigated the effects of different concentrations of Livol powder in Rohu \((Labeo rohita) feed for 112 days. The results indicated that after receiving 2 mg/kg Livol powder, the fish showed the highest SGR and FCR. In the current study, the LAB count increased as a result of the CSP inclusion in the diet, which may suggest that the high fiber content in CSP may contribute to LAB increase. LAB are believed to positively affect growth, FCR and survival rate \((19, 20)\). Therefore, the enhancement of these parameters, may be related to the LAB count increase. However, further studies are needed.

Fish skin mucus is well known to be the first barrier of defense \((21)\), since it contains different immune proteins such as complements, lysozyme, immunoglobulins, protease and lectins \((22)\). Previous studies have demonstrated that fish skin immunity can be improved through the administration of different additives to their diet such as vitamins \((23)\), probiotics \((24)\), prebiotics \((25)\), synbiotics \((26)\) and herbal components \((2, 27, 28)\). Based on the available information, no studies were found on the effects of CSP on either fish or shellfish skin mucus immunity. The results of the current study indicated that the antibacterial activity in rainbow trout mucus against \(S. iniae, A. hydrophila, S. faecium, S. luteus, and Y. ruckerii\) increased along with the dietary CSP level of inclusion. However, the mucosal antibacterial activity against all five strains of bacteria decreased with the increment of CSP levels in the diet from 40 to 50 g/kg, an outcome that may indicate that the overdose of CSP supplement can have detrimental effects. Similar results were obtained from other researches \((29)\) which surveyed the effects of Peppermint \((Mentha piperita) on the skin antibacterial activity of rainbow trout against \(Y. ruckeri\). The results presented here also showed that the activity of the immune proteins and total protein content in the skin mucus increased significantly along with CSP presence in the diet. Similar results have been reported in relation to the use of other herbal substances such as garlic \((5, 30)\), onion \((2, 31)\), peppermint \((32)\), etc., which confirm the increase in the level of blood and mucosal immunity in fish and crustaceans. Given that mucosal lysozyme plays an active role in bactericidal activity, it is likely that mucosal antibacterial activity would be enhanced by stimulated mucus activity \((33)\). This is because the immune proteins in mucus, such as lysozyme and protease, play a vital role in destroying the walls of in-
RESEARCH ARTICLE

The physiological and nutritional status of an aquatic organism plays a significant role in skin mucus immunity such as bactericidal activity (33). In recent studies, it has been found that different parts of milkweed leaf powder (35) latex (36), and seed oil (37) have antibacterial activity. Consequently, it can be assumed that including CSP in the diet causes the increase of the activity of skin mucus compounds (lysoenzymes, proteases, immunoglobulins, etc). However, the role of gut lactic acid bacteria (LAB) increase on improving mucosal immunity cannot be ignored.

In conclusion, this study we demonstrated the suitability of C. persica seed powder as feed additive in rainbow trout O. mykiss diet. The best level of inclusion was found to be 40 g/kg CSP added to the diet, capable of improving the mucosal immune responses, the gut microbiota composition and the growth performances.

Material and methods

Fish preparation

A total of 360 healthy rainbow trout [O. mykiss (Walbaum 1792)] (average weight 11.50 ± 3.64 g), were obtained from a local fish supplier in Mashhad, (Khorasan Razavi, Iran) and maintained at a density of 200 individuals per cement tank (1 m³). The fish were acclimatized to the laboratory conditions and kept under observation for clinical health for 14 days prior to starting the experiment. The physico-chemical parameters of water, such as temperature (16.15 ± 3.5˚C), dissolved oxygen (7.90 ± 0.14 ppm) and pH (7.1 ± 0.5), were maintained in accordance with the standard values for rainbow trout culture. All experiments were done according to FUM animal ethics.

CSP preparation

C. persica produces lots of seeds which are flat and brown, and have tufts at one end. Seeds used in this study was obtained from nature (Kerman, Jiroft , Iran). After removing tufts, seeds were dried in an oven at 50°C for 24 h and then ground into powder before adding them to the diets (38).

Diet preparation

A control diet (45.03 g/kg BW, crude protein; 18.40 g/kg, crude lipid; 18.80 J/kg, crude energy) was developed by WUFFDA (Windows User-Friendly Feed Formulation; University of Georgia, Georgia, USA) software (39) (Table 4). To prepare the experimental diets, C. persica seed powder (CSP) at the inclusion levels of 0, 10, 20, 30, 40 and 50 g/kg for basal diet was employed. CSP was replaced with Carboxymethyl cellulose (CMC). Diets were isonitrogenous, isoenergetic. Feed ingredients were converted into a uniform paste by adding water. Thereafter, the dough was passed through a meat grinder with 2 mm diameter holes (40). The obtained “spaghett” were cut into pellets and dried at 30°C for 24 h, and stored at 4°C until use. The experiment was carried out in the form of a completely randomized design. Each diet was fed to three replicate tanks for 56 days and rainbow trouts were fed 2% of their body weight thrice daily.

Vitamin premix contains (mg kg-1) E, 30; K, 3; Thiamine, 2; Riboflavin, 7; Pyridoxine, 3; Pantothenic acid, 18; Niacin, 40; Folacin, 1.5; Choline, 600; Biotin, 0.7 and Cyanocobalamin, 0.02 (provided from kimia rosh© Gorgan, Iran).

The experimental fish were weighted at the end of the trial on a digital balance with the accuracy of 0.01 g. Survival rate, growth parameters, feed conversion ratio (FCR), hepatosomatic index (HSI) and Gastro-Somatic Index (GaSI) were calculated as follows (41);

Specific Growth Rate (SGR) = [(Ln final weight (g)–Ln initial weight (g))/experiment days] ×100
Feed Conversion Ratio (FCR) = (Feed consumed (g)/Weight gain (g))
Condition factor = (Final weight (g)/Total length^3 (cm)) \times 100
Survival rate (%) = (Final individual numbers/Initial individual numbers) \times 100
Hepato-Somatic Index (HSI) = (Liver weight (g)/Total body weight (g)) \times 100
Gastro-Somatic Index (GaSI) = (Gut weight (g)/ Total body weight (g)) \times 100

**Chemical analyses**

Crude protein (Kjeldahl method), crude fat (Saxhot method), gross energy (parr; electric bomb), crude fiber, ash (electric furnace at 550°C for 6 h), phosphorus (titration with vanadium molybdate) and nitrogen-free extract contents of CSP and control diet (Table 1) were measured according to the standard methods (42).

**Skin mucus immunological parameters**

At the end of the experiment, the skin mucus samples were collected according to the protocol described by Ross et al. (2000) with some modifications, to monitor antibacterial activity. Briefly, anesthetized fish (clove powder (5 mg/l)) were placed for 2 min in individual plastic bags containing 5 ml of 50 mM NaCl (30 fish per treatment, one by one without pooling). Thereafter, the mucus samples were centrifuged at 1500×g for 10 min at 4°C and the supernatant was stored at -80°C until use.

Protein concentration was determined according to the method of Lowry et al. (1951), using bovine serum albumin as a standard. The absorbance was read using a spectrophotometer (Biochrom, Libra S12) at 750 nm. Skin mucus alkaline phosphatase (ALP) activity was estimated using Pars Azmoun (Pars Azmoun Co, Iran) commercial kit according to the manufacturer's protocol. Lysozyme activity was determined based on the lysis of the lysozyme-sensitive Gram-positive bacterium *Micrococcus lysodeikticus*, according to the protocol described by Demers (43). Alternative complement activity was assayed by using rabbit red blood cells (R RBI) (44) and based on the guidance released by Neissi et al. (45).

**Skin mucus antibacterial activity**

The skin mucus antibacterial activity of *O. mykiss* fed CSP was checked out against two gram-negative fish pathogens, *Yersinia ruckeri* PTCC 1888 and *Aeromonas hydrophila* PTCC 1889, using the disk diffusion method (46). 0.1 ml of each bacterium was mixed with the nutrient agar medium (Merck, Germany). Paper discs (6 mm diameter) were inoculated with 150 ml of the mucus sample and kept for 20 min to allow the mucus placed on the medium to be absorbed. Plates were incubated for 24 h at 37°C. Finally, the diameter of the inhibition zone was measured by Image J (1.45s) software.

**Intestinal bacterial analysis**

At the end of the experiment, the fish were anesthetized with clove powder (5 mg/l), disinfected with 70% ethanol and the whole gut was removed (47). Enumeration of the total viable count (TVC) of heterotrophic bacteria and *lactobacillus* bacteria (LAB) in the intestine was assessed using 1 g of posterior intestine sample. The samples were homogenized in 9 ml normal sterile saline solution (0.90% w/v of NaCl) and dilutions prepared to 10^4. Then, 0.1 ml of the saline solution was spread over duplicate plates of plate count agar (for total heterotrophic bacteria) and MRS agar (for LAB). The plates were incubated at room temperature for 72 h. The bacterial colonies were counted in each sample based on the colony forming unit (CFU/g) (colony count \times dilution-1= CFU / g intestine) (48).

**Statistical analysis**

All percentage data were transformed using the arcsine method. Levene's test was used to confirm the homogeneity of variance, while the Kolmogorov-Smirnov test was used to determine the normality of data (Zar, 1999). The data were analyzed using one-way ANOVA and Duncan's multiple range test was applied to determine any significant differences among the treatments (p < 0.05).

ABSTRACT

This study examined the effects of skim-milk based extenders supplemented with proline and glutamine on motility, lipid peroxidation and enzymatic antioxidant status of cooled-stored equine sperm and determined the role of seminal plasma as well. The semen was collected with artificial vagina. In experiment 1, native semen was diluted in skim-milk based extender containing 5mM glutamine and 3mM proline, stored at 5°C and analyzed at 4, 24 and 48 hours storage for motion parameters. In experiment 2, semen was centrifugated, sperm pellet resuspended in the extenders and stored at 5°C for 4 hours to determine motion parameters. The level of catalase, glutathione peroxidase activity and malondialdehyde formation was determined for all samples at 4 hours. Glutamine and proline significantly preserved the percentage of motile sperm (76.5 ± 2.7 and 79.4 ± 1 vs 69 ± 1.4), increased the progressive motility of cold-stored semen (66.1 ± 2.5 and 73.7 ± 2.9 vs 56.2 ± 1.4), increased catalase activity, and decreased malondialdehyde. However these effects were disappeared after seminal plasma removal. We conclude that glutamine and proline would amplify the antioxidant activity of equine cold-stored semen and preserve its motility. This effect seems to be related to interactions with seminal plasma.

GPX: glutathione peroxidase
Introduction

The use of artificial insemination in world equine industry eliminates the detrimental effects of animal transportation and transmission of diseases, as well as providing more opportunities for breeders to make use of genetically superior stallions [1]. The techniques of cooling and transportation of semen, as well as cryopreservation allows artificial insemination to take place, irrespective of the location and availability of stallions. However, it is obvious that the fertility rate for artificial insemination is lower than that for natural service [2].

Oxidative stress is an important factor associated with the decline in fertility of stored semen. During refrigerating storage, the number of viable sperms decreases [3], fertility rate declines [4], and damaging intracellular reactive oxygen species (ROS) is found to be accumulated [5, 6]. Semen is composed of spermatozoa and seminal plasma, endowed with enzymatic and non-enzymatic defense mechanisms against oxidative stress [7]. Seminal plasma is a complex mixture of organic and inorganic substances with controversial effects on sperm properties [8, 9], and is thought to influence the fertility outcome of the cooled-shipped semen. Some studies have revealed that seminal plasma exerts deleterious effects on sperm during cooling transportation, and that the separation of seminal plasma reduces those effects and maximizes post-cooling motility [10, 11]. Removal of seminal plasma has been described to result in increased percentage of motile sperm and membrane and chromatin intactness, both during refrigerated storage, as well as delayed cryopreservation [12-15]. Nevertheless, some studies propose that removal of seminal plasma eliminates the potential protective capacity provided by the SP [16, 17]. This potential can be related to antioxidant properties and ROS scavenging capability of seminal plasma, which can even be enhanced through interacting with semen extenders [18]. However, centrifugation of cooled sperm is thought to be detrimental to sperm motility [13, 19]. The equipment for seminal plasma removal is not always available at the location of semen collection. In cases where farm is far from laboratory, semen must be cooled-shipped and it is necessary to preserve equine semen in extender for several hours without removing seminal plasma. Hence, during transportation, sperms are exposed to seminal plasma. In these cases the modification of semen extender composition has been proposed as an alternative to separation of SP [20]. The protection of cooled equine semen against oxidative stress and loss of motility might be improved by adding some specific components to extenders.

Some amino acids are known to be involved in protecting several types of animal cells against hypothermia [21-23]. The amino acid proline can preserve membrane structure of sperm cells [24], reduces LPO, protects against free radical damages, inhibits intracellular ice formation and influences the motility and velocity [25, 26]. Likewise, amino acid glutamine is known to play a regulatory role in several cell-specific processes [27, 28]. Based on these information, glutamine and proline have been proposed as efficient additives in semen extenders to function as cryoprotectant in several species [24, 27-31]. However, the results of studies considering these amino acids as cryoprotectant have been controversial in terms of improving either the maintenance of motility or the fertility of cooled semen.

The hypothesis of this study was that addition of proline and glutamine to extender could improve the longevity of stallion sperm motility during cold storage. The study was designed to investigate whether the skim-milk based extender supplemented with proline and glutamine could preserve stallion semen for 48 hours of cold transportation. Moreover, the effects of seminal plasma on the enzymatic antioxidant status of extended semen in the presence of these amino acids were evaluated. It will be determined whether the inclusion of glutamine and proline in the extender in the presence and absence of seminal plasma, have any effect on the motility, lipid peroxidation, and enzymatic antioxidant status of stallion sperm during storage at 5°C. Such studies can help breeders to optimize protocols for the transportation of stallion’s spermatozoa, which must be maintained for long intervals.

Results

Experiment 1

Mean percent motile and progressive sperm motility of raw semen at the time of collection were 79.5 ± 1.2 and 73.2 ± 1.5, respectively. Effects of semen treatments on the percentage of motile sperm and progressive motility of stallion semen stored up to 48 hours are presented in Table 1. In each group of extenders, (E1, E2, and E3) all the parameters at 4 hours storage were significantly different relative to 24 and 48 hours storage (p < 0.05). At 4 hours storage, the percent motile sperm of E2 (76.5 ± 2.7) and E3 (79.4 ± 1.9) were significantly higher than E1 (69 ± 1.4) (p < 0.05). The progressive motility of E2 (66.1 ± 2.5) and E3 (73.7 ± 2.9) were significantly higher than E1 (56.2 ± 1.4) (p < 0.05). At 24 and 48 hours storage, percent motile sperm and progressive motility of E2 an E3 were significantly higher than E1 (p < 0.05) (Table 1). At 4 hours storage, the MAD, BCF and STR of E2 and E3 were significantly decreased compared to E1. The VCL and LIN of E3 were significantly decreased compared

Different numbers in each row and different letters in each column are indicative of statistically significant differences at *p* < 0.05. E1: control extender; E2: the control extender supplemented with 5 mM glutamine, E3: the control extender supplemented with 3 mM proline. Values are mean percentages ± SEM of ten split ejaculates (2 ejaculates x 5 stallions). The control extender contained: INRA82 +2% egg yolk + 2.5% (v/v) glycerol.

to E1 and E2. At 24 and 48 hours storage, differences in kinematic parameters between three groups were not statistically significant (Table 2).

**Experiment 2**

As shown in Table 3, after 4 hours storage, the percent motile sperm and progressive motility of equine spermatozoa in E4 were not different with E5 and E6. At 48 hours of storage the motility parameters of E4, E5 and E6 were reduced to near zero.

The results shown in Table 4 indicate that the content of MDA is significantly different in E4 (0.7 ± 0.08 nmol/mg protein) relative to E5 (0.18 ± 0.08 nmol/mg protein) and E6 (0.39 ± 0.04 nmol/mg protein) (*P* < 0.05). The MDA of E4 is also significantly higher than E2 (0.35 ± 0.09 nmol/mg protein) and E3 (0.3 ± 0.03 nmol/mg protein). There is no difference between MDA content of E1 with E2, E3 and E4. The activity of GPX remained unchanged in all groups. The activity of CAT enzyme was significantly different between E1 (35.4 ± 7.8 KU/ mg protein), E2 (166.2 ± 21 KU/ mg protein) and E3 (154.6 ± 60 KU/ mg protein). Differences between E4, E5, and E6 were not statistically significant (Table 4).

**Discussion**

In the present study, the effects of glutamine and proline on motion and kinematic parameters, as well as lipid peroxidation and antioxidant capacity of cooled stallion semen, and their relationship to seminal plasma were tested. The results of experiments 1 and 2 revealed that addition of proline and glutamine significantly preserved the motion parameters of cooled stallion semen over time. In the absence of SP, none of the motion parameters were affected by two used amino acids.

The positive effects of glutamine and proline on stallion sperm subjected to cryopreservation have been reported [27, 30, 32]. The present study revealed that these two amino acids improved the motion parameters of cold-stored native semen, but in groups lacking seminal plasma, motility was unaffected. It was previously proven that in the absence of seminal plasma, addition of extenders composed of nonfat, dried skim milk solids and glucose provide adequate support for the preservation of spermatozoa motility [10]. Our study showed compensatory effect for proline and glutamine in preservation of equine spermatozoa motility in the presence of seminal plasma.

Although the reduction in spermatozoa1 motion parameters in extended stallion semen after 24 hours of cold storage has previously been reported [11], the role of seminal plasma in motion characteristics of sperm in different studies is contradictory. The reduction [9], improvement [10, 11, 33] and no change [34] in spermatozoa1 motility after seminal plasma removal have been reported. Two studies [35, 36] demonstrated no effect for SP during cooling of the stallion semen up to 12 and 24 hours, respectively. Whereas another study [12] speculated that long exposure to seminal plasma in cooled stallion sperm may be responsible for the irreversible loss of motility and DNA degradation. It is thought that centrifugation for SP removal eliminates decapacitating factors in SP [37], resulting in premature capacitation [38]. This has been related to the protective roles of some components of seminal plasma, which is variable in different stallions [39]. The results of Moor et al., indicated that prolongation of the semen incubation time causes undesir-

able effects, probably due to the presence of seminal plasma [40]. Our results revealed that the decrease in motion parameters of stallion sperm during cold storage was compensated by addition of extenders containing amino acids. This positive effect of amino acids became evident only in the presence of seminal plasma. It seems that the interaction between proline and glutamine with seminal plasma is responsible for such compensatory effects.

Based on our results, glutamine and proline enhanced CAT activity in the presence of SP. This is when the motility of sperm is improved. Interestingly, MDA was decreased in groups containing amino acids irrelevant to seminal plasma. Seminal plasma contains organic and inorganic substances such as high levels of enzymatic and non-enzymatic antioxidants. It seems that the interaction between proline and glutamine with seminal plasma is responsible for such compensatory effects.

Several studies have shown that supplementation of semen extenders with glutamine and proline can improve total sperm motility of cooled ram sperm, protect sperm cells against free-radical-induced damage, and provide cryoprotection to ram sperm by minimizing lipid peroxidation both at pre-freeze and post-thaw semen [48]. Rudolph [49] stated that proline may interact with phospholipid bilayers and stabilize the membrane structures during freezing. Similarly, in this study, inclusion of glutamine and proline in extenders containing amino acids...
proline to the extender reduced malondyaldehyde formation, which was concomitant with positive changes in motion parameters, which shows that lipid peroxidation was inhibited by proline and glutamine during cooling storage. This was confirmed by another study showing that the positive role of proline for the motility of freeze-thawed stallion spermatozoa [30]. In the same way, Pagl [50] explained the dysfunctional role of plasma membrane and mitochondrial membrane in the loss of cooled-stored sperm motility.

We also found that CAT activity, as well as motion parameters increase in cooled semen in the presence of proline and glutamine with SP. Bucak [23] hypothesized an antioxidative effect for glutamine through increasing CAT activity, and Baumber [51] demonstrated that CAT enzyme prevents negative effects of ROS on motility and DNA fragmentation of equine sperm. On the other hand, Kancofer [18] proposed that the interactions among components of extenders and antioxidative enzymes of seminal plasma boost the antioxidative/oxidative capacity of stallion seminal plasma. This means that some factors in extenders influence activities of antioxidant enzymes present in seminal plasma. In addition, amino acids in combination with glycerol affect calcium ATPase of sperm cells [52], as well as the phosphate groups of sperm plasma membrane phospholipids for protection against thermal shock [53]. In this research, we found that removal of seminal plasma significantly reversed the effect of glutamine and proline on antioxidative enzymes. Therefore, it appears that these amino acids need a certain amount of seminal plasma for enhancing enzymatic antioxidative capacity during cooling storage, which preserve motion parameters of cold-stored sperm as well.

It is concluded that the skim-milk extender containing glutamine and proline amplify the antioxidative activity of equine cold-stored semen, as well as motility preservation. This effect seems to be related to interactions with seminal plasma.

**Material and methods**

**Semen collection**

Five fertile stallions aged between 4-9 years were used in this study. They were on a routine semen collection schedule and fed balanced diet. Semen samples were collected using artificial vagina, and two ejaculates were obtained from each stallion. They had already been included in previous semen cryopreservation program, and had been shown to have good semen freezability [30].

**Reagents**

Unless otherwise indicated, all reagents used in the experiments were obtained from Sigma-Aldrich Company (St. Louis, MO).

BM: INRA82 medium + 20mM HEPES/L + 2% centrifuged egg yolk and 2.5%, v/v glycerol

**Preparation of extenders and semen**

All extender media were derived from basal medium (BM), composed of INRA 82 medium (0.5 L saline solution: 25 g glucose, 1.5 g lactose, 1.5 g raffinose, 0.25 g sodium citrate dihydrate, 0.41 g potassium citrate, 50,000 IU penicillin, 50 mg gentamycin and 0.5 L skim milk) reaching final concentration of 2% (v/v) centrifuged egg yolk, 20 mM HEPES and 2.5% v/v glycerol (pH: 6.8) [32].

Aliquots of BM extender were supplemented with different concentrations of proline and glutamine (Merck corporation, Germany): 0 (E1 and E4 as control group), 5 mM glutamine (E2 and E5) and 3 mM proline (E3 and E6) (pH: 6.6-6.8). Osmotic pressure of the extender media was measured with an automatic osmometer (OSMOMETER 800c l, SLAMED, Germany) (Table 5).

A total of ten Ejaculates were collected using a Missou-ri-model artificial vagina. After removing the gel fraction from the ejaculate by filtration through gauze, the gel-free portion of the ejaculate was evaluated for volume and progressive motility, as well as measuring spermatozoa concentration by a hemocytometer. One part of the raw semen was diluted 1:1 by adding: basal medium as the control (E1), basal medium containing 5mM glutamine (E2) and basal medium containing 3mM proline (E3). Then, it was cooled to 5°C, and stored for 48 hours.

The other part of native semen was submitted to centrifugation for seminal plasma removal, and spermatozoa were resuspended to a concentration of 25x10⁶ motile sperms/ml in three types of extenders: basal medium as the control (E4), basal medium containing 5mM glutamine (E5), and basal medium containing 3mM proline (E6). Then, it was cooled to 5°C and stored for about 4 hours.

**Experimental design**

In Experiment 1, routine semen analysis was performed in cooled semen E1, E2 and E3 at 4, 24 and 48 hours storage at 5°C.

In experiment 2, changes in malondyaldehyde (MDA) formation (TBARS concentration as an indicator of lipid peroxidation), enzymatic antioxidant activities of catalase and glutathione peroxidase as well as CASA parameters for all 6 groups were monitored in cooled semen samples after 4 hours storage.

**Evaluation of Semen Motion and kinematic parameters**

Semen quality analysis was performed using the CASA system (HFT CASA- Housemand Fanavar- Tehran- Iran) to evaluate the sperm motion parameters. Sperm samples (10 mL) were diluted in 0.5 mL of phosphate-buffered saline (PBS) and subjected to CASA. Five field images (minimum of 500 cells) were randomly selected and analyzed for the following parameters: motile sperm and progressively motile sperm percentages, as well as sperm kinematic parameters, including amplitude of lateral head displace-
ment (ALH), beat cross frequency (BCF), curvilinear velocity (VCL), straight line velocity (VSL), average path velocity (VAP), linearity (LIN = VSL/VCL), mean angular displacement (MAD), wobble (WOB= VAP/VCL) and straightness (STR = VSL/VAP).

Biochemical analysis

Biochemical assays were performed on the sperm samples homogenized by an ultrasonic homogenizer (FAPAN, Iran); then, total protein level of sperm was measured using a Bio-Rad protein assay kit (Bio Rad, Hercules, CA, USA). The levels of MDA, GPX and CAT were measured in protein content of sperm cells.

Concentration of malondialdehyde, as indices of the LPO, was determined colorimetrically using the method of Buege & Aust [54]. Briefly, 0.1 mL of sperm homogenate was treated with 2 mL of TBA–TCA–HCl reagent, placed in water bath for 15 min, cooled, centrifugated and then the absorbance of supernatant was measured against reference blank at 535 nm (Unico 2100, United Products Instruments, Inc., Dayton, NJ, USA). Concentrations were calculated using an extinction coefficient of 1.56 × 10⁵ mol/L/cm. The MDA concentration was expressed in nmol/ml.

Activity of glutathione peroxidase was estimated according to the method of Lawrence & Burk [55], in which the reaction mixture containing potassium phosphate buffer, EDTA, sodium azide, NADPH, glutathione reductase and reduced glutathione was incubated for 5 min at 25°C, and after adding H₂O₂ and sperm homogenate, the absorbance changes at 340 nm was monitored for 1 min. One unit of GPX activity was reported as μmol NADPH consumed per min per mg sperm protein, using the appropriate molar absorptive coefficient for NADPH (6220 mol/L/cm).

Activity of sperm catalase was assayed according to the method of Goth [56]. Briefly, sperm homogenate samples were incubated in the reaction mixture composed of potassium phosphate buffer, sodium azide, NADPH, glutathione reductase and reduced glutathione to the method of Goth [56]. Briefly, sperm homogenate samples were incubated in the reaction mixture composed of potassium phosphate buffer, sodium azide, NADPH, glutathione reductase and reduced glutathione, and then frozen. چکیده
شیوع تومورهای بوستی سگ از شیراز، ایران

محمد عباس زاده حسینی، فاطمه نمازی، فروغ زارعی کردوشی

گروه گازی دانشگاهی دانشکده دامپزشکی، دانشگاه شیراز، شیراز، ایران
گروه پاتوبیولوژی دانشگاهی دانشگاه شیراز، شیراز، ایران

متالعه حاضر بر روی ۴۲ سگ با تشخیص هیستوپاتولوژیک تومور بوستی که از سپتامبر ۲۰۱۲ تا دسامبر ۲۰۱۷ به دانشگاه دامپزشکی دانشگاه شیراز ارجاع شده بود، انجام شد. همه موارد بجز تومورهای غدید پستان مورد بررسی قرار گرفت. نوع تومور از نظر هیستوپاتولوژی شروع، جنس، سن و توزیع محل تومورها توصیف شد. در علاوه بر این، مطالعات منتشر شده بر روی تومورهای بوستی سگ از سایر مناطق جغرافیایی مورد بررسی قرار گرفت و با نتایج مطالعه حاضر مقایسه شد. از نظر هیستوپاتولوژی، ۱۵ نوع تومور مختلف تشخیص داده شد. شروع تومورهای اپیتیوی، مزائیته، لیپوماتوئی و لنفوهیستوپاتولوژیک به ترتیب ۱/۱۵، ۹/۶۲، ۷/۳۲ و ۰/۲۳ درصد بود. شایع ترین تومورها آدنوم غددی چربی (۲۳/۲۱٪) کارسپین سلول سنگفرشی (۹/۱۷٪) و لیپوما (۹/۱۷٪) بودند. فراوانی این تومورها بیش از سایر تحقیقات بود. اگرچه توضیح واضحی برای این تفاوت های جغرافیایی وجود ندارد، اما می‌توان از مکان جغرافیایی، اثرات محیطی و جمع‌بندی معامله و نزد مورب باش. تربر شایع ترین نوع سگ در این مطالعه ۴/۳۴٪ بود. یافته‌های حاضر در مورد سگ‌های مبتلا به تومورهای بوستی مختلف، با حاصل‌های آنتومومیکی نشان می‌دهد که تفاوت قابل توجهی در این پارامترهای مهم بین سگ‌های ایرانی و سایر نقاط جهان وجود ندارد. این اطلاعات بیش از این درباره جمع‌بندی سگ‌های ایرانی منتشر نشده است.

چکیده

بیماری نیوکاسال یک عفونتی و اکیپاردر در بیماری از گونه‌های پرندگان است که خصائص زیراژی به صنعت طیور دنیا وارد می‌کند. این مطالعه با هدف تعیین جهت باینی، دفع ویروس و پاسخ ایمنی به دنبال آلودگی با ویروس حاد نیوکاسال جدا شده از ماکیان کوشتی در قروال‌های حاوی حساسیت و واکسن انگیشت‌های جدید، به‌جوار قروال‌های پرندگان نوروز نیوکاسال (620TEID50) با واکسن B1 به روش قطره جوشی واکسن‌های شدن. دو هفته بعد، هر پرنده در گروه‌های 1 و 2 یک بیماری نیوکاسال در حجم ۲۰۰ میکرویلتر (۲۰۰ میکرویلتر در چشم) جنگلی شد. همیشه گروه‌های ۶۲ هفته زیر نظر بودند. نمونه‌های سوآب در معقله زمانی مختلف تهیه و از نظر آلودگی به ویروس نیوکاسال به سیلیک واکنش زنجیره‌ای به منشأ مکوسی (RT-PCR) بررسی گردیدند. نامینه‌ای نیز با آزمایش مماثل از هماکلوترونی تکه‌های جوشی قروال‌های جنگلی نیوکاسال (RT-PCR) در ۱۰۵روزهای ۱ و ۳ گروه بکار می‌گرفت. قروال‌های هر گروه ۲ نشانه‌های بی امکانی افسردگی و انحراف سر را بررسی کردند. از ۲۰ پرنده در گروه دفع ویروس نیوکاسال فقط در قروال‌های غیر واکسن‌سپرده در روزهای ۱۲ تا ۱۴ بعد از جنگل مشاهده گردید. میزان رشدی ویروس به سیلیک سوآب نای (۵۰ درصد) بیشتر از سوآب کلوک (۱۰۰ درصد) بود. تغییرات سروکلومیک در قروال‌های آلوده نیز معنی دار بود. نتیجه گیری‌های منتشری می‌شود که ویروس حاد نیوکاسال موجود در گله‌های ماکیان ایران، بیماری زایی کمی برای قروال‌ها دارد و واکسن قطره جوشی B1 می‌تواند محورهای خویش ایجاد کند.

چکیده

هورمون رشد اثر انتقال میتوئنیک و آنتی-آپوتوزیس دارد و زمایی که به این ترتیب بیان شود ممکن است تکنیک و تغییرات شکل سلولی را افزایش دهد. این مطالعه به بررسی اثرات تمرین مقاومتی و تزریق هورمون رشد بر سطوح در گرددش 1 و IGF-1 و نسبت IGFBP-3 و IGF-1 را انجام داد. در موسه‌های صحراوی نر و بچه به طور تصادفی به گروه کنترل (نام: G0) و گروه تمرین مقاومتی (نام: G1) اختصاص داده شدند. برآمده تمرین مقاومتی شامل معادن کنار گذاشته در هفته سه، پنج تکرار علیه یک کیلوگرم وزن ایران، به طور مداوم گام و پایین رفتن روز به روز در هفته سه، پنج تکرار یک کیلوگرم وزن ایران. G1 و G0 بر اساس مقدار (یک/روز، سه/روز/سیستم 1) در طول هفته تمرین، هورمون رشد IGF-1 (mg/l) یکبار هفته، زمانی مشابه، برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از ارزش هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 به طور معنی‌داری در گروه تمرین مقاومتی در مقایسه با گروه کنترل کاهش یافت و این معنی‌داری در نهایت، احساس سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح سرمی IGF-1 و IGFBP-3 از هفته هفته ای در اثر تجزیه و تحلیل واریانس یک طرفه (ANOVA) برای مقایسه سطوح S
نقش گیرنده فاکتور آزادگانده کورتیکوتروپین (CRF) بر اثرات بی اشتهایی القا شده با LPS در جوجه های نوزاد

انتشار نهایی: 2019-07-27

چکیده

گیرنده CRF با پاسخ‌های فاز جاد (APR) است. لیپوساکارید (LPS) به شکل متدندای برای تقلید و القا استفاده می‌شود. مکانیسم بی اشتهایی همراه با APR در جوجه شناخته نشده است. در مطالعه حاضر درگیری احتمالی فاکتور آزادگانده کورتیکوتروپین (CRF) بر اثرات بی اشتهایی القا شده با LPS در جوجه های نوزاد مورد بررسی قرار گرفت. برای این هدف، دوزهای LPS متفاوت به شکل مرکزی و محیطی برای بررسی آثار آن بر مصرف (LPS) توسط حاضر اعمال شد. سپس اثرات تزریق درون بطنی به عنوان انتگونیست گیرنده CRF به بی اشتهایی القا شده با LPS در جوجه های نوزاد توسط بررسی قرار گرفت. مصرف LPS به دنبال تزریق مرکزی و محیطی CRF باعث گرفتاری بیشتر در درک آن لیپوساکارید و پیش درمان با astressin به عنوان راهکار مناسب برای کاهش اثرات تزریق مرکزی LPS در جوجه های نوزاد در بی اشتهایی القا شده با LPS توانسته باشد. درک آن LPS در بی اشتهایی القا شده با LPS درک آن LPS به عنوان راهکار مناسب برای کاهش اثرات تزریق مرکزی LPS در جوجه های نوزاد در بی اشتهایی القا شده با LPS توانسته باشد.
اثر زهر مارهای افعی ایرانی، زنجانی و لطیفی بر زنده مانی سلول های بنیادی مزانشیمی استخراج شده از مغز استخوان رت بصورت داخل و برون تئیه

چکیده
زهر مار یک ترکیب پیچیده با مواد مختلف با خصوصیات فارماکولوژیک است. هدف از این تحقیق، بررسی اثر زهر مارهای افعی (لطیفی) بر رفتار سلول های بنیادی مزانشیمی در محیط کشت تیمار in vivo و in vitro بود. سلول ها با گلفت های مختلف آبیکورونتایا (زنجانی) و افعی لطیفی (لطیفی) بر زنده مانی سلول های بنیادی مزانشیمی در میکروکوئس 100 μl/ μg، 50 μl/ μg، 25 μl/ μg، و 12.5 μl/ μg در شرایط in vitro و در 24، 48 و 72 ساعت کشت تیمار شدند. سلول ها در شرایط in vivo نیز به شکل آزمایش تیمار شدند. نتایج نشان داد که سلول های تیمار شده با زهر ۲ برای زهر مار زنجانی و لطیفی به ترتیب بعد از 48 و ۲۴ ساعت بود. نتایج آزمایش in vivo نشان داد که سلول های تیمار شده با زهر افعی لطیفی باید ۲۴ ساعت در شرایط in situ با تکثیر نصیب را از پا افتاده و در مقایسه با کنترل داشتند. زهر مارهای زنجانی و لطیفی می‌توانند برتر کنند و رفتار سلول های بنیادی مزانشیمی اثر بگذارند.

تأثیر استفاده از سطوح مختلف پودر بذر استبرق (Calotropis persica) بر شاخص‌های رشد، ایمنی و میکروبیوتیوی روده ماهی قزل آلای رنگین کمان (Oncorhynchus mykiss)

حمیدرضا احمد‌نیا مطلق، امید صفری، ماریا پانولسی،

گروه پایه جیره، دانشکده مهندسی کشاورزی، دانشگاه تکنولوژی استان هرمزگان,

مطالعه ای به مدت هشت هفته به بررسی امکان استفاده از شش سطح (0.00، 0.02، 0.03، 0.04 و 0.05 گرم بر کیلوگرم جیره پایه) پودر بذر استبرق (Calotropis persica) در رژیم غذایی ماهی قزل آلای رنگین کمان (Oncorhynchus mykiss) در قالب طرح کاملا تصادفی انجام شد. برای احراز آزمایش، 2367 چه ماهی (3/4 ± 1/1 گرم) به مدت 6 روز تحت تیمار قرار گرفتند. براساس نتایج، افزایش پودر دانه استبرق تا 0.05 گرم در کیلوگرم باعث تقویت توجهی در رشد و وزن و تعداد باکتری‌های اسید لاکتیک روده در مقابل با شاهد شد (P<0.05). بهترین نتایج مربوط به نیازهای انگریزی، شاخص‌های کنادی و روده آی در تیمارهای روده در مقایسه با شاهد که (P<0.05) به دست آمد. نتایج آنی باکتری‌آل مکوس‌پوسنت، لیزوزمن و آلکالین قفسانی بالاترین سطح آب در تیمار 0.05 گرم در کیلوگرم نشان داد (P<0.05). بر اساس نتایج به دست آمده، پودر دانه استبرق به میزان 0.05 گرم بر کیلوگرم باعث بروز تأثیرات مثبتی ایمنی، ایمنی و میکروبیوتیوی روده ماهی قزل آلای رنگین کمان باشد.
تأثیر محیط نگهدارنده حاوی گلوتامین و پرولین بر روی استرس اسیداتیو و پارامترهای حرکتی منی نریان در زمان نگهداری به صورت سرد شده

نجمه داویدان، علی کدیور، ابراهیم احمدی

این مطالعه اثرات محیط نگهدارنده غی شده با اسیدامینه‌های پرولین و گلوتامین را بر تحرک اسپرم، پراکسیدازیون لیپیدی و وضعیت آنتی اسیداتیوی منی سرد شده از صورت نمود و همچنین نقش پاسامایان می‌را نیز مشخص کرد. منی با ورزش مصنوعی جمع‌آوری شده و با محیط نگهدارنده حاوی 5 میلی مول گلوتامین و 3 میلی مول پرولین مخلوط شده و در دماي 5 درجه سانتی‌گراد نگهداری شدند. در آزمایش اول، پارامترهای حرکتی در زمان‌های 1، 24 و 48 ساعت مورد اندازه‌گیری قرار گرفت . در آزمایش دوم، پلت حاصل از سانتریفیوز منی، در محیط یاپای محتوی آمینو اسیدهای مخلوط شده و پس از جهر ساختن نگهداری در دمای 5 درجه سانتی‌گراد و در آزمایش اول، نتایج نشان داد که گلوتامین و پرولین بطور مشخص بهبود حفظ پارامترهای حرکتی اسپرم منی را نیز در دماهای 24 و 48 ساعت تحت تأثیر قرار می‌گیرند. نتایج نشان داد که گلوتامین و پرولین در تکثیر منی در حذف سمینال با رابطه منفی داشته و این اثرات آن‌ها می‌تواند باعث بهبود کاهش طول جیره اسپرم منی شود. نتایج این مطالعه نشان می‌دهد که اسیدامینه‌های پرولین و گلوتامین باعث بهبود حرکتی اسپرم منی شدند و بهبودی آنتی اسیداتیوی منی را نیز در دمای‌های مختلف باعث افزایش حفظ منی شد و بهبودی در حرکتی اسپرم منی را نیز در دمای‌های مختلف باعث افزایش حفظ منی شد.
The Editor-in-Chief would like to extend his sincere gratitude to the following reviewers for evaluating and assessing manuscripts published in this issue of IJVST journal.

SCOPE

Iranian journal of Veterinary Science and Technology (IJVST) is a peer-reviewed and multi-disciplinary journal that supports important research advances in veterinary medicine and subject areas relevant to veterinary medicine including anatomy, physiology, pharmacology, bacteriology, biochemistry, biotechnology, food hygiene, public health, immunology, molecular biology, parasitology, pathology, virology, etc. Contributions related to clinical sciences including large and small animal medicine, poultry disease, diseases of equine species and aquaculture are welcomed. Articles can comprise research in basic sciences, as well as applied veterinary findings and experimental studies with impacts on diagnosis, treatment and prevention of animal diseases. Manuscripts are published as Original articles, Review articles, Case reports, or Short communications.
GENERAL GUIDELINES

1. Submitted manuscripts should not be previously published elsewhere and should not be under consideration by any other journal.
2. The submitted manuscript should be accompanied by a written statement signed by the corresponding author on behalf of all the authors that its publication has been approved by all coauthors, stating that the whole manuscript or a part of it has not been published.
3. The corresponding author should provide all co-authors with information regarding the manuscript, and obtain their approval before submitting any revisions.
4. Ethics: Authors must state that the protocol for the research project has been approved by the Ethics Committee of the institution within which the work was undertaken. Authors are responsible for animal welfare and all statements made in their work.

OPEN ACCESS POLICY

Iranian Journal of Veterinary Science and Technology is a fully Open Access journal in which all the articles are available Open Access. There is no cost to the reader or author. Since all costs are covered by Ferdowsi University of Mashhad Press, there is no cost to the author, or through article processing charges.

COPYRIGHT

Accepted manuscripts become the permanent property of the IJVST and may not be reproduced, in whole or in part, without the written permission of the Editor. The Copyright assignment form can be downloaded from IJVST website.

SUBMISSION

Authors should submit their manuscript in electronic format directly through the IJVST website (ijvst.um.ac.ir) along with a letter to editor signed by the author to whom correspondence should be addressed. Please ensure that Email addresses are university/governmental addresses and full postal addresses are included on the title page of the manuscript. List of files and forms which should be completed and submitted are:
- Manuscript (template file can be downloaded from IJVST website)
- Title page (template file can be downloaded from IJVST website)
- Tables (template file can be downloaded from IJVST website)
- Figures
- Endnote manuscript library file (Vancouver style can be downloaded from IJVST website)
Guide for Authors

PREPARATION OF MANUSCRIPT

Manuscripts should be written in English, with Abstract in both English and Persian (where applicable), typewritten in MS Word program, double-spaced, in 12-point “Times New Roman” font on A4 paper size. Authors are requested to reserve margins of 2.5 cm all around the pages. Manuscript should also have line numbers. All pages of the manuscripts should also be enumerated.

Original Articles should contain Title page, Abstract, Keywords, List of Abbreviations, Introduction, Results, Discussion, Materials and methods, References, and Figure legends. Tables and figures should be appended as individual files.

Review Articles should contain Title page, Abstract, Keywords, List of Abbreviations, Introduction, appropriate sections depending on the subject, Conclusions and future directions. Tables and figures should be appended as individual files. The review article should provide an update on recent advances in a particular field. Authors wishing to submit review articles should contact the Editor with an outline of the proposed paper prior to submission.

Case Reports should include Title page, Abstract, Keywords, List of Abbreviations, Introduction, Case Presentation, Results and Discussion, and References. Case reports should not exceed 2000 words (excluding the references) and should include no more than two tables or figures. Tables and figures should be appended as individual files.

Short Communications should not exceed 2000 words (excluding the references) and include no more than two tables or figures. They should include Title page, Abstract, Keywords, List of Abbreviations, the text summarizing results with no other divisions, and References. Tables and figures should be appended as individual files.

Title Page

Full Title Page should include title (concise and informative), author(s) (including the complete name, department affiliation, and institution), running head (condensed title) (≤ 50 characters, including spaces), name and address of the authors to whom correspondence and reprint requests should be addressed, Acknowledgements, Author contributions, and Conflict of interest.
Acknowledgements

Personal acknowledgement, sources of financial support, contributions and helps of other researchers and everything that does not justify authorship should be mentioned in this section, if required.

Author contributions

Authors are required to include a statement to specify the contributions of each author. The statement describes the tasks of individual authors referred to by their initials. Listed below is an example of author contributions statement:
Conceived and designed the experiments: HD, SS. Performed the experiments: SS. Analyzed the data: HD, SS, MMM, ARB. Research space and equipment: HD, MMM, ARB. Contributed reagents/materials/analysis tools: HD. wrote the paper: SS, HD.

Conflict of interest

All authors must disclose any financial and personal relationships with other people or organizations that could inappropriately influence (bias) their work. Examples of potential conflicts of interest include employment, consultancies, stock ownership, honoraria, paid expert testimony, patent applications/registrations, and grants or other funding. If there are no conflicts of interest then please state this: ‘The authors declare that there is no conflict of interest’. This form can be downloaded from IJVST website.

Abstract

Abstract (in English and Persian) no more than 250 words should contain the purpose of the study, findings and the conclusion made on the basis of the findings. Authors who are not native Persian speakers may submit their manuscript with an abstract in English only. Abbreviations and reference citations may not be used in the abstracts.

Keywords

For indexing purposes, each submitted manuscript should include three to seven keywords, following the abstract and preferably chosen from the Medical Subject Headings (MESH). Keywords should express the precise content of the manuscript.

Introduction

Introduction should be as concise as possible, and clearly explain the main objective and hypothesis of the investigation.

Results

Results indicate the results of an original research in a clear and logical sequence. Do not repeat data that are already covered in tables and illustrations. In manuscripts describing more than one animal, all animals should be assigned a case number.

Discussion

Discussion should include the answer to the question proposed in the introduction and emphasize the new and important aspects of the study and the conclusions that follow from them. It could include the implication, application, or speculation of the findings and their limitations, relate the observations to other relevant studies, and links the conclusions with the goals of the study. Recommendations, when appropriate, may be included.

Materials and methods

Materials and methods should be described in sufficient details to allow other workers to reproduce the results. Specify any statistical computer programs used. The methods of data collection and use of statistical analysis will be checked by
the referees and if necessary, a statistician. Drugs and therapeutic agents, reagents, softwares and equipments should be given in the format: name (trade name, manufacturer name, city, country), e.g. Statview 5 (SAS Institute, Inc., Cary, NC, USA).

References
Must be up-to-dated and limited to those that are necessary. Lists of references should be given in numerical order in the text, and in the reference list. Please use Vancouver style. To download the Vancouver Style follow the link in IJVST website which could be used in the Endnote software.

Example piece of text and reference list:
An unhealthy diet, obesity and physical inactivity play a role in the onset of type 2 diabetes, but it has been shown that increased physical activity substantially reduces the risk [1], and participation in regular physical activity is one of the major recommendation of the evidence based guidelines for the primary prevention of diseases [2]. According to the 2004-05 National Health Survey, more than half a million Australians (3.5% of the population) have diabetes mellitus which had been medically diagnosed and most of these people have the Type 2 condition [3]. Gestational diabetes is also on the increase, rising steadily between 2000-01 and 2005-06 [4]. Approximately two thirds of those with diabetes have been prescribed medication [3], but it is of concern that a recent review of the literature found that many people do not take their medication as prescribed [5]. Many patients also self monitor the disease by measuring their blood glucose levels with a glucose meter but Song and Lipman [6] have concerns about how well this is managed.

References for the above example:

Tables
Please submit tables as individual files and editable text and not as images. Place all table notes below the table body. Each table should have a title which is followed by explanation of results shown in the table. Use of vertical rules must be avoided. Tables should be self-explanatory, and clearly arranged. Tables should provide easier understanding and not duplicate information already included in the text or figures. Each table should be typewritten with double spacing on a separate file and numbered in order of citation in the text with Arabic numerals. Each table should have a concise heading that makes it comprehensible without reference to the text of the article. Explain any nonstandard abbreviations in a footnote to the table.

Figures
Figures must be submitted in individual files (format: TIFF, Dimensions: Width: 789 – 2250 pixels at 300 dpi Height maximum: 2625 pixels at 300 dpi, Resolution: 300 – 600 dpi, file size: less than 10 MB, Text within figures: Arial or Symbol font only in 8-12 point). The text and other labels should be placed in the figure as un-compressed layers. Each figure should have a title which is followed by explanation of results shown in the figure. Figures should be numbered in order of citation in the text with Arabic numerals.
The bar diagrams should be provided with shading of black, white, gray, cross-hatching, vertical stripes, and horizontal stripes. Please do not use different shades of gray. The axes of diagrams should have titles and units. Also, the source file of the image (Excel etc.) should be provided for typesetting.

Illustrations should be numbered as cited in the sequential order in the text, with a legend at the end of the manuscript. Color photographs are accepted at no extra charge. The editors and publisher reserve the right to reject illustrations or figures based upon poor quality of submitted materials.

If a published figure is used, the publisher’s permission needs to be presented to the office, and the figure should be referenced in its legend.

**Use of Italics**

Gene symbols, Latin terms (i.e. *in vivo*, *in vitro*, *ex vivo*, *in utero*, *in situ*, and etc.) and species scientific names (using the binomial nomenclature), should be typed in italics, while the first letter of the genus name must be capitalized (i.e. *Homo sapiens*).
Publication ethics

Iranian Journal of Veterinary Science and Technology is aligned with COPE’s (Committee on Publication Ethics) best practice guidelines for dealing with ethical issues in journal publishing and adopts the COPE guidelines. The journal members (editor, editorial board and the journal manager) have agreed to meet the purposes and objectives of the Journal.

Ethical guidelines for authors:

Authorship Criteria:
IJVST requires authors to confirm that they and their co-authors meet all four criteria for authorship based on the guidelines of The International Committee of Medical Journal Editors (verbatim as follows):

1. Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work; AND 2. Drafting the work or revising it critically for important intellectual content; AND 3. Final approval of the version to be published; AND 4. Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

The section “Author Contributions” in the manuscript should illustrate and clarify who contributed to the work and how. If a contributor does not meet all four above criteria should be acknowledged in the “Acknowledgements” section of the article.

Author agreements and conflict of interest:
Written authorization from all authors for publication of the article is mandatory for IJVST to start the review process. This form entitled “Conflict of interest declaration and author agreement form” must be signed and completed by all authors. This statement and signatures certifies that all authors have seen and approved the manuscript being submitted. Also, the authors by signing this form warrant that the article is the Authors’ original work, that the article has not received prior publication and is not under consideration for publication elsewhere, and that the corresponding author shall bear full responsibility for the submission.

Editors and members of editorial board as authors:
Editor and members of editorial board are excluded from publication decisions when they are authors or have contributed to a manuscript.

Open access policy:
Iranian Journal of Veterinary Science and Technology is a fully Open Access journal in which all
the articles are available Open Access. There is no cost to the reader or author. Since all costs are covered by Ferdowsi University of Mashhad Press, there is no cost to the author, or through article processing charges. The article will be published under the Ferdowsi University of Mashhad Press open access policy. This means that the article will be made freely available online for non-commercial use immediately upon publication.

**Ethical guidelines for Peer reviewers:**

Iranian Journal of Veterinary Science and Technology (IJVST) follows and adheres to COPE Ethical Guidelines for Peer Reviewers. IJVST peer reviews all submitted manuscripts with contents in the scope of the journal. The process has been explained in the section “Peer Review Process”.

**Ethical guidelines for Editor:**

Iranian Journal of Veterinary Science and Technology regarding the responsibilities of the editors follows and adheres to COPE Ethical Guidelines for editors. The main guidelines are summarized in the guide to ethical editing from COPE.
**PEER REVIEW PROCESS**

Iranian Journal of Veterinary Science and Technology peer reviews all submitted manuscripts with contents within the scope of the journal.

*Initial assessment:*

The structural format of the paper, quality of figures, and format of references are evaluated within 5 days from the time of submission.

*Initial screen:*

The manuscripts are evaluated by editor and a member of editorial board (depending to the field of study) for the scope, sufficient originality, having a message that is important to the general field of Veterinary Medicine, quality of data, novelty, English language, and overall manuscript quality. This stage is performed within 2 weeks in order to not waste authors’ time, allowing them to submit the manuscripts to another journal. Those manuscripts which are evaluated as not-appropriate in the initial review will be rejected at this stage. We aim to reach a first decision on all manuscripts within two or three weeks of submission.

*External review:*

The manuscripts which are found to be appropriate after the initial screen, will be sent for external review by experts in the related field. We have prepared a checklist for reviewers that summarizes their evaluation of the manuscript. The items in this checklist are:

1. **TITLE** is clear and adequate
2. **ABSTRACT** clearly presents objects, methods and results.
3. **INTRODUCTION** is well-structured and provides rationale for experiments described.
4. **MATERIALS AND METHODS** is sufficiently explained and is detailed enough to be reproduced.
5. **RESULTS** are clearly presented and are supported by figures and tables.
6. **DISCUSSION** properly interprets the results and places the results into larger research context, and contains all important references.
7. Conclusions are logically derived from the data presented.
8. English Language/style/grammar is clear, correct, and unambiguous.
9. Figures and tables are in good quality and well-designed and clearly illustrate results of the study.
10. References are appropriate.
11. There are no issues relating to author misconduct such as plagiarism and unethical behavior.
12. The article is important and worthy of publication.

*Final Decision:*

Based on reviewers’ recommendations a final decision is made by the editor and if needed the help of a member of editorial board (depending to the field of study). Decisions will include accept, minor revision, major revision with and without re-review, and reject. We aim to reach a final decision on each manuscript as soon as their review results are available.
